1 INTRODUCTION

1.1 Purpose

The NASA Plankton, Aerosol, Cloud, ocean Ecosystem (PACE) mission is designed to observe the global ocean and atmosphere and provide extended data records of ocean ecology, biogeochemistry, atmospheric aerosols and clouds. The primary instrument on PACE, the Ocean Color Instrument (OCI), is a UV-VIS-NIR imaging spectrometer with additional discrete channels in the SWIR. Two other instruments have been contributed to PACE with more limited requirements. Both are multi-angle, polarization sensitive (MAP) imagers. The Hyper-Angular Rainbow Polarimeter 2 (HARP2) is a wide swath, four VIS-NIR channel sensor, while the Spectro-Polarimeter for Exploration (SPEXone) has a narrower swath but provides hyperspectral data.

PACE has requirements to produce ocean, aerosol, and cloud parameters from the OCI instrument. Additionally, a number of advanced science data products have been identified to be produced on a best-effort basis from all three instruments. An essential activity to these efforts is the validation of data product quality. This process involves the comparison of satellite data products to independently gathered observations of ocean, atmosphere, and land parameters. It also entails consideration of differences of scale, acquisition time, expectations of uncertainty, statistical sampling, and other matters by both satellite and independent measurements.

The overall plan for validation of PACE data is described in "PACE Science Data Product Validation Plan" (hereafter referred to as the PVP, see reference details at end of this section). This document describes the required and advanced science data products to be validated, the PACE science data product validation program and its timeline, and the elements necessary for successful PACE validation. It also contains a brief section describing the requirements for field campaign(s) in support of PACE validation, while noting a forthcoming document describing these requirements in detail – this one.

This document describes the basis for, and requirements of, a PACE Postlaunch Airborne eXperiment (PACE-PAX). PACE-PAX will be conducted roughly 9 months following the PACE launch and will deploy a variety of airborne and coordinated ground assets for the purpose of gathering validation and assessment data.

There are several reasons for augmenting PVP ground and ocean-based measurements with a dedicated airborne field campaign. These include, but are not limited to, the following.

1. **New products will be created from PACE observations**. They will need to be validated to assess quality and guide algorithm development. Dedicated field campaigns can make specific observations to this end. Furthermore, many of these products will be the result of multi-parameter algorithms, and retrieval capability for one geophysical property may depend on another, e.g., the accuracy of ocean chlorophyll-a pigment concentration products depends on the quantity and characteristics of atmospheric aerosols that are a part of atmospheric correction. Field campaigns that gather concurrent observations of multiple geophysical parameters enable a useful assessment of new products, particularly if they are made with airborne analogs of PACE instruments.

2. **Field campaigns that include airborne assets can provide for a different scale of observation** (spatial and temporal) than other validation sources, and a link between point measurements at the surface and the PACE orbital observatory.
3. **Airborne field campaigns can reposition assets within the spacecraft swath.** Due to its narrow swath, PACE's SPEXone instrument will have relatively few coincident observations with ground validation sites within the 3-year mission lifetime. Airborne assets can be directed to fly within the SPEXone swath during an overpass, adding many validation observations to an otherwise limited dataset.
4. **Airborne assets can validate PACE radiometric and polarimetric observations** prior to their use for retrieval of geophysical parameters.
5. **Remote sensing success depends on observation geometry, season, and time of day**, which can be directly targeted with field campaigns.
6. **Field campaigns can focus on specific systems, processes, or phenomena** to verify they are properly accounted for in the satellite retrieval scheme**.**

The characteristics of PACE-PAX are described in this document, including a further discussion of how field campaign observations fit within the larger scope of PACE validation, what independent measurements are required, the logistical considerations for carrying out the mission, and the support required to properly measure, analyze, and archive the observed data.

1.2 PACE mission overview

The original definition of the PACE mission is included in *Responding to the Challenge of Climate and Environmental Change: NASA's Plan for Climate-Centric Architecture for Earth Observations and Applications from Space,* as a bridge mission to aerosol (particulate matter in the atmosphere), cloud, and ocean ecosystem observing mission(s) described in the National Research Council's 2007 Decadal Survey of Earth Science for NASA, NOAA and USGS, entitled *Earth Science and Applications from Space: National Imperatives for the Next Decade and Beyond.* As such, PACE will produce heritage products that provide continuity with existing climate and Earth system records, and also create new advanced products for emerging science questions related to the Earth's changing climate.

The PACE observatory includes three instruments. The Ocean Color Instrument (OCI) is a hyper-spectral scanning radiometric imager that will measure from the ultraviolet (UV) to shortwave infrared (SWIR) with a view-angle tilt to avoid ocean surface reflected sun glint. OCI is the primary instrument on PACE, and it is in development at the NASA Goddard Space Flight Center (GSFC). OCI will produce heritage ocean, aerosol and cloud products, and advanced products that take advantage of hyper-spectral and UV sensitivity. PACE will also include two contributed multi-angle polarimeters (MAP), instruments that maximize observed information with the use of multiple geometry measurements and determination of the polarization state of light. Developed at the University of Maryland, Baltimore County (UMBC), the Hyper-Angular Rainbow Polarimeter (HARP2) instrument is a wide swath imager intended for determination of cloud and aerosol optical parameters through the utilization of hyper-angle measurement capability. The Spectro-Polarimeter for Exploration (SPEXone) is a highly accurate (although narrow swath) hyperspectral MAP intended for the identification of detailed aerosol (and other) parameters. It is being developed by a consortium in the Netherlands that includes Airbus and the Netherlands

Institute for Space Research (SRON). Table 1 contains details on the measurement characteristics of each instrument.

Table 1 Instrument specifications for OCI, HARP2 and SPEXone. Recreated from Table 2 of Werdell et al., 2019. * The mission carries a goal of extending the shortest wavelength to 320nm. + There is a 2-day coverage when limited to solar and sensor viewing angles of 75˚ and 60˚, respectively.

	OCI	HARP2	SPEXone
UV-NIR range (bandwidth)	Continuous from 340 to 890nm* in 5-nm steps (5)	440, 550, 670 (10), and 870 (40) nm	Continuous from 385 to 770 nm in 2-4nm steps
SWIR channels (bandwidth)	940 (45), 1,038 (75), 1,250 (30), 1,378 (15), 1,615 (75), 2,130 (50) and 2,260 (75) nm	None	None
Polarized bands	None	All	Continuous from 385 to 770 nm in 15-45nm steps
Number of viewing angles	One, with fore-aft instrument tilt of ±20˚ to avoid sun glint	10 for 440, 550 and 870 nm and 60 for 670 nm (spaced over 114˚)	5 (-57˚, -20˚, 0˚, 20˚, 57˚)
Swath width	±56.6˚ (2,663 km at 20˚ tilt)	±47˚ (1,556km at nadir)	±4˚ (100 km at nadir)
Global coverage	1-2+ days	2 days	~30 days
Ground pixel	1 km at nadir	3 km	2.5 km
Institution	GSFC	UMBC	SRON/Airbus

PACE will be launched into an ascending polar orbit at a nominal spacecraft altitude of 676.5 kilometers, with a local crossing time of 13:00 and inclination angle of 98°. Observations will cover the globe regularly, and the length of time required to observe the entire globe depends on the instrument swath. As shown with other instrument characteristics in Table 1, the wider swath OCI and HARP2 instruments require 1-2 days for global coverage, while the narrow swath SPEXone instrument will require roughly 30 days. For that instrument, overflights of fixed ground validation sites will be much less frequent.

PACE is classified as a Category 2 mission, per the criteria in NASA Procedural Requirement (NPR) 7120.5E, NASA Space Flight Program and Project Management Requirements. The mission classification is C according to NPR 8705.4B, Risk Classification for NASA Payloads. The scheduled launch date is in 2023.

1.3 Mission requirements for validation

The PACE Program Level Requirements Agreement (PLRA) and Mission Requirements Document (MRD) (see section 1.4) provide the requirements pertaining to the PACE Science Data Product Validation Program:

"Post-launch field validation work is required to evaluate the PACE science data products in Tables 1 and 2 within 12 months of commissioning. The PACE validation programs (provided by HQ PACE Science) shall include the following for the mission duration:

a) Shipboard and aircraft campaigns as required to collect the data products defined in Tables 1 and 2.
b) Autonomous instrument systems that collect continuous records of any of the individual data products defined in Tables 1 and 2."

Tables 1 and 2 referenced in this quote are replicated as Tables 2 and 3, respectively, in this document. These are the required data products to be produced by the PACE Project Science (PS) and Science Data Segments (SDS). Project Science is responsible for data product quality and must therefore validate by comparing to independent observations. In addition, NASA Headquarters (HQ) PACE Program Science competes both the PACE Science and Applications Team (SAT) and the PACE Validation Science Team (PVST) which contribute algorithms, data, insight, and other guidance to the PS and SDS to ensure date quality.

The required products in Tables 2 and 3 must be validated within 12 months of PACE spacecraft commissioning. These required products are only for the OCI sensor, and, with some exceptions, can be considered 'Heritage,' that is, produced by previously launched missions. The MAP instruments (HARP2 and SPEXone) are contributed to the PACE mission with requirements limited to "do no harm" to the rest of the spacecraft, so there are no required products from those instruments. However, the full list of expected PACE products (Tables 4-10) represents new measurements and science that all three PACE sensors (OCI, HARP2, and SPEXone) may address. The science and algorithms supporting many of these products are in development by the SAT, PS, and instrument teams. An important aspect of this development is the validation of these new products. Some, but not all, can be validated using the resources called for in the PVP. The remainder require additional efforts and resources, as described in this document. An evolving list of products are captured on the PACE website (https://pace.oceansciences.org/data_table.htm). The process by which algorithms are selected, tested, and implemented in the PACE SDS is described in the PACE Science Data Product Selection Plan (SDPSL).

Table 2 Required OCI ocean color data products. The requirements for ocean color products stated in this table are defined for 50% or more of the observable deep ocean (depth>1000 m).

Data Product	**Baseline Uncertainty**
Water-leaving reflectances centered on (±2.5 nm) 350, 360, and 385 nm (15 nm bandwidth)	0.0057 or 20%
Water-leaving reflectances centered on (±2.5 nm) 412, 425, 443, 460, 475, 490, 510, 532, 555, and 583 (15 nm bandwidth)	0.0020 or 5%
Water-leaving reflectances centered on (±2.5 nm) 617, 640, 655, 665 678, and 710 (15 nm bandwidth, except for 10 nm bandwidth for 665 and 678 nm)	0.0007 or 10%
Ocean Color Data Products to be Derived from Water-leaving Reflectances	
Concentration of chlorophyll-a	
Diffuse attenuation coefficients 400-600 nm	
Phytoplankton absorption 400-600 nm	
Non-algal particle plus dissolved organic matter absorption 400-600 nm	
Particulate backscattering coefficient 400-600 nm	
Fluorescence line height	

Table 3. Required OCI aerosol and cloud data products. The requirements in this table are defined for 65% or more of the observable atmosphere. Each requirement is defined as the maximum of the absolute and relative values when both are provided. This table represents threshold aerosol and cloud data products, all of which can be produced by OCI alone.

Data Product	Range	Baseline Uncertainty
Total aerosol optical depth at 380 nm	0.0 to 5	0.06 or 40%
Total aerosol optical depth at 440, 500, 550 and 675 nm over land	0.0 to 5	0.06 or 20%
Total aerosol optical depth at 440, 500, 550 and 675 nm over oceans	0.0 to 5	0.04 or 15%
Fraction of visible aerosol optical depth from fine mode aerosols over oceans at 550 nm	0.0 to 1	±25%
Cloud layer detection for optical depth > 0.3	NA	40%
Cloud top pressure of opaque (optical depth > 3) clouds	100 to 1000 hPa	60 hPa
Optical thickness of liquid clouds	5 to 100	25%
Optical thickness of ice clouds	5 to 100	35%
Effective radius of liquid clouds	5 to 50 μm	25%
Effective radius of ice clouds	5 to 50 μm	35%
Atmospheric data products to be derived from the above		
Water path of liquid clouds		
Water path of ice clouds		

As previously mentioned, Tables 2 and 3 describe PACE required products from the OCI sensor. These are to be validated as described in the PVP, with additional assessment as described in this document. Table 4 lists the radiometric products that will be produced at top of atmosphere (TOA) from all three sensors. The "Level-1B" data format refers to calibrated data at TOA, while "Level-1C" is a data format for which all sensor observations are represented on a compatible, equal area grid (L1Cplan). The latter is especially important for multiangle observations by SPEXone and HARP2 and will serve as the starting point for algorithms that determine geophysical (Level-2) products using data from multiple sensors. For example, the proposed microphysical aerosol parameters from polarimetry algorithm (MAPP, Stamnes et al., 2018) will start with either SPEXone or HARP2 data at Level-1C and combine that with SWIR observations by OCI to retrieve coupled atmosphere and ocean optical parameters.

Table 4 Calibrated Radiometry and Polarimetry, as observed at sensor.

Product	Description and Use	Units	Availability	Status
Spectral top-of-atmosphere radiances from OCI	Spectral radiance observed at the top of the atmosphere.	W m^{-2} um^{-1} sr^{-1}	Level-1B at 1 km^2 at nadir, daily; Level-1C 5.2 km^2, daily	Standard product
Spectral top-of-atmosphere radiances and polarimetry from SPEXone	Spectral radiance and polarimetry observed at the top of the atmosphere, for all sensor viewing angles.	Various	Level-1B at TBD km^2, daily; Level-1C at 2.6 km^2, daily	Standard product

Spectral top-of-atmosphere radiances and polarimetry from HARP2	Spectral radiance and polarimetry observed at the top of the atmosphere, for all sensor viewing angles.	Various	Level-1B at TBD km^2, daily; Level-1C at TBD km^2, daily	Standard product

2 PACE-PAX BACKGROUND

Airborne observations of the land, ocean, and atmosphere by NASA began at the Ames Research Center, which started by acquiring three high altitude U-2 aircraft (designated ER-2 at NASA) and a Convair 990 in 1969 (Bilstein, 1989). Early field campaigns acknowledged the benefit of combining aircraft, land, and satellite observations. An example of ground and aircraft validation of satellite observations, the Large Area Crop Inventory Experiment (LACIE), validated crop yield predictions from the Earth Resources Technology Satellite-1, later renamed Landsat-1 (e.g., MacDonald, 1977). Other missions utilized airborne resources to test prototype instruments and measurement techniques, such as described in Sellers et al. (1976) for UV observations of stratospheric ozone, and Hoge and Swift (1981) to map ocean chlorophyll with a lidar. An

especially extensive effort was the Global Atmospheric Research Program (GARP, e.g., Perry, 1975) which employed roughly 40 ships, 13 aircraft and 4,000 scientists and technicians for multiple field campaigns. This was a multi-agency, international, effort devoted to harnessing satellite, ground, and aircraft observations to improve numerical weather prediction, understanding of climate, and other aspects of the atmosphere. Field campaigns have also been used to support mission formulation, by flying prototype instruments to test observation strategies. Recent examples of this include the Hyperspectral Infrared Imager (HyspIRI) field campaigns (Lee et al., 2015) and the Aerosol Characterization from Polarimeter and Lidar (ACEPOL, Knobelspiesse et al., 2020) field campaign, which was in support of the Aerosol, Cloud, Ecosystems (ACE) mission pre-formulation study (Da Silva et al., 2020). Field campaigns primarily devoted to scientific objectives can also serve the purposes of satellite mission development and validation. Ongoing examples include aerosol-cloud campaigns such as Aerosol Cloud meTeorology Interactions oVer the western ATlantic Experiment (ACTIVATE, Sorooshian et al., 2019) or those focused on a better understanding of ocean biogeochemistry, such as EXport Processes in the Ocean from Remote Sensing (EXPORTS, Siegel et al., 2016, 2021).

The difficulty of gathering validation observations from existing field campaigns was highlighted in the first PACE Science Team, which noted the rarity of observations useful for MAP algorithm development (e.g., https://pace.oceansciences.org/docs/sci2017_proxy.pdf).

A dedicated field campaign is required to support the PACE mission. Experience with pre-launch field missions have demonstrated that validation of new products from PACE requires a targeted effort (PACE-PAX). This is especially the case for the capabilities of MAPs and OCI's UV and hyperspectral sensitivity, from which an extensive set of new geophysical products are derived that are not regularly observed on the ground.

To organize of ways in which a dedicated field campaign can be used to validate PACE observations, we have identified a set of observational objectives. The enumerated reasons for conducting a dedicated PACE validation field campaign, in Section 1.1, corresponds to this list, which is based upon successful validation efforts by previous missions. These will be used as a guide to design the PACE dedicated field campaign as well. Starting from these objectives, we will model the flow of a Science Traceability Matrix (STM, e.g., in the PACE SDT report), starting from observational objectives, to the measurement approach needed to satisfy that objective, to the requirements for successful observation and other needs. We will use the analogous name Validation Traceability Matrix (VTM). Once established, the VTM will be used for trade studies while planning the PACE post-launch field campaign. For example, different aircraft, instrumentation, or deployment location scenarios can be compared in the context of their ability to meet observational objectives. This can be accomplished with the use of an adapted Bayesian search theory (BST, Stone, 1989), where estimates of probable success can be assigned to the requirements of each field campaign scenario, and via the VTM, be translated into the probability of meeting an objective. Combined with a decision algorithm, this approach can also be used during a field campaign to guide daily operations (Small et al. 2011). A simplified version of this was used during the ACEPOL field campaign, where a 'scorecard' of measurement objectives informed flight planning.

3 VALIDATION TRACEABILITY MATRIX (VTM)

The VTM is used to connect validation objectives with the design requirements for a successful validation field campaign. The VTM identifies the resources required to conduct a field campaign, and the means to compare different design options. Our implementation makes use of numerical assessments of different components of the VTM, which can be incorporated into planning tools by the use of BST (this aspect is described in more detail in Section 8).

The VTM also can be used to determine the impacts of descoping or loss of elements, and, when combined with BST, a useful tool for mission operations while underway. The categories of information in the VTM are described in the subsequent sections.

3.1 Validation objectives

The objectives are high level goals for the validation, from which all other components of the VTM flow. They were briefly described in the introduction, and more details are provided here.

Objective 1: Validate new retrieval parameters. This is the primary focus of PACE-PAX, addressing the output from algorithms described in the PACE data products table (https://pace.oceansciences.org/data_table.htm) that are not a part of the required products in Tables 2 and 3. We limit our scope to radiometric and polarimetric products, with a focus on observations that can be made from aircraft and those that are complementary to aircraft observations. Many of the products will be produced by algorithms of provisional maturity, validation is necessary to ensure further maturity (see https://science.nasa.gov/earth-science/earth-science-data/data-maturity-levels). An important component of this is the use of airborne proxies of the instruments on PACE. With these proxies, algorithms can be tested in controlled (or at least known) environments, without the need for concurrent PACE measurements. This has been the only feasible approach to validate developing algorithms in the PACE prelaunch era (e.g., Fu et al., 2019, Gao et al., 2020, Puthukkudy et at., 2020), and will remain important after launch.

Furthermore, many algorithms retrieve multiple parameters simultaneously (as described for the MAPs by Dubovik et al., 2014, 2019, Gao et al., 2019, 2020, 2021, Hasekamp et al., 2011, 2019, Puthukkudy et al., 2020, Stamnes et al, 2018) while others require the output of other algorithms as an input (see Frouin et al., 2019 for a description of the use of atmospheric correction for Ocean Color remote sensing). Validation of these algorithms thus requires simultaneous observation of multiple parameters to meet this objective.

Aerosol single scattering albedo (SSA) is an example of the type of parameter validated with this objective. Defined as the ratio of scattering to total extinction by aerosols, SSA is not a required product for OCI, but is a climatologically important parameter that can be retrieved from MAPs (Mishchenko et al., 2004, Knobelspiesse et al., 2012, Hasekamp et al., 2019) or inferred from OCI's UV spectral capability (e.g., Torres et al., 2007). Algorithms to determine SSA from PACE measurements are under development by the SAT, project science office, and instrument teams. All these algorithms retrieve multiple parameters and cannot be fully validated as part of the PVP. A specific field effort must therefore be made to validate SSA, and similar products, from PACE.

Objective 2: Assess spatial and temporal scale impact on validation. This is important to link ground, aircraft, and satellite observations. Spatiotemporal mismatch between these measurements can be an apparent source of discrepancy unrelated to retrieval accuracy. To complicate matters, this spatial and temporal variability differs among geophysical parameters and conditions (Sayer, 2020, Dickey et al., 2006). We must therefore determine appropriate validation scales, using spatial or temporal surveys. Remote sensing measurements, at a higher spatial (or temporal) resolution than PACE, are best suited for this purpose, as are extended measurements under conditions of known variability.

Objective 3: Validate within the instrument swath of all PACE instruments. While the OCI and HARP2 instruments have a wide swath with 1-to-2-day global coverage, SPEXone has a much narrower (~100km at nadir) swath, resulting in an approximately 30-day global coverage. This means that comparisons of SPEXone to fixed ground locations (such as AERONET) will be infrequent. As an example of the consequences of this narrow swath, we investigated the number of aerosol optical depth (AOD) MODIS-Aqua (e.g., Hsu et al., 2013) to AERONET-OC (Zibordi et al., 2010) validation matchups in the SeaWiFS Bio-optical Archive and Storage System archive (SeaBASS, Fargion et al., 2001) for a three-year period (2012-2015) as a surrogate for consequences of instrument swath. In this period, 1,164 and 916 matchups can be found with the subset of MODIS measurements corresponding to OCI and HARP2 swaths, respectively. Restricting to the SPEXone swath results in only 80 matchups in the same time period. Three years is the planned PACE observatory lifetime, which calls into question the ability to validate narrow swath observations with ground measurements alone. The solution is to position validation assets within the swath of an expected SPEXone observation. This has been a successful approach for other narrow swath instrumentation, such as for the Cloud-Aerosol Lidar and Infrared Pathfinder Satellite Observation instrument (CALIPSO, McGill et al., 2007, Hlavka et al., 2012).

Objective 4: Validate radiometric and polarimetric parameters prior to their use for retrieval of geophysical parameters with instrument proxies (Table 4). This activity supports PACE in-flight calibration activities. For example, during the ACEPOL field campaign (ACEPOL, Knobelspiesse et al., 2020), a team characterized the reflectance of Rosamond Dry Lake in California, providing a bright surface calibration reference. This type of characterization is routinely used to directly validate satellite observations uncertainty models or be used to characterize airborne proxy remote sensing instruments which are subsequently compared to satellite observations.

Objective 5: Target specific geometries, season, and time of day. Retrieval capability depends on observation geometry (the solar and sensor zenith and azimuth angles). This is especially the case for the MAP instruments (e.g., Hasekamp and Landgraf, 2005, Hasekamp et al., 2019, Knobelspiesse and Nag, 2018). Furthermore, a field campaign can be used to investigate the influence that geometry has on retrieval success.

Objective 6: Focus on specific processes or phenomena to verify they are properly accounted for in the satellite retrieval scheme. A variety of atmospheric, ocean, and land surface parameters will be retrieved from PACE observations, and data processing must have the capability to identify when the appropriate algorithms are to be used. Furthermore, those algorithms must be robust for the range of possible conditions that are to be observed. Dedicated field campaigns can seek to observe specific geophysical conditions and ensure retrieval success.

3.2 Measurement objectives

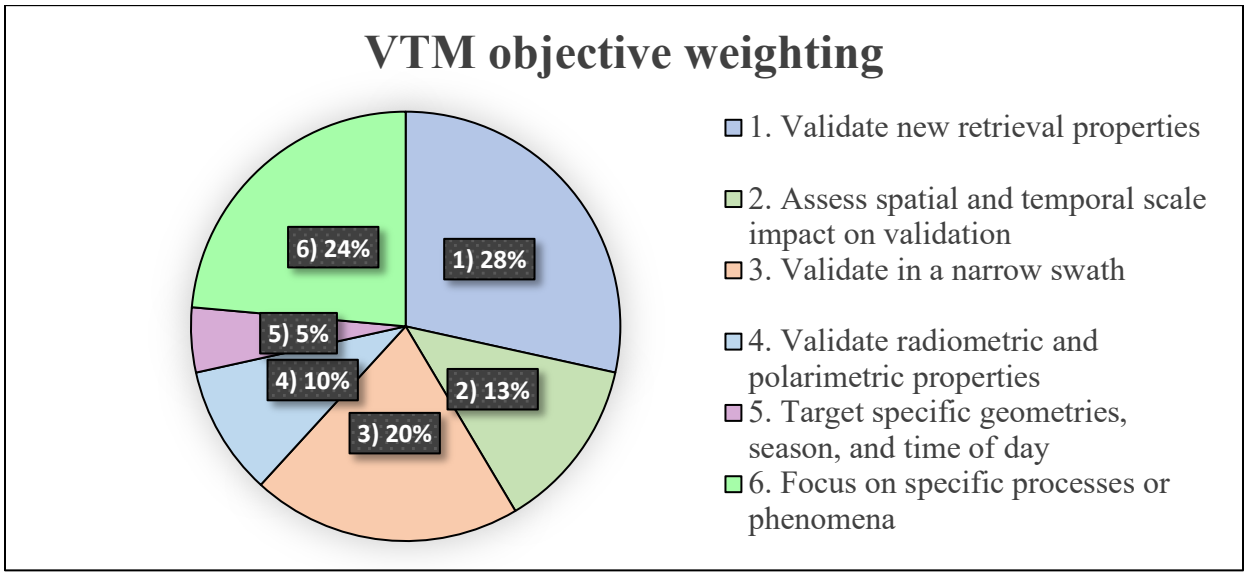
Each top-level objective is further split into measurement objective categories, such as "cloud parameters" or "(cloud-free) aerosols over the ocean". These categories comprise a set of geophysical parameters retrieved from algorithms that derive them simultaneously, and/or for validation of parameters that have broadly similar mission requirements.

3.3 Measurement objective importance

This is a subjective, numerical measure used to provide a relative weighting of measurement objectives (higher means more important). This weighting is used in assessment of field campaign plans (Section 4), and previous field missions (Section 5) and in support of planning during an ongoing field campaign (Section 8). It should express not only the importance of the measurement objective, but the algorithm maturity for PACE data production of the measurements comprising an objective. The numerical values of this weighting are irrelevant so long as they are consistently applied for all measurement objectives, as it is normalized by the sum of all weights in later analysis.

While inherently intuitive, the importance weighting in the VTM is a means to prioritize measurement objectives in a collective fashion. The PACE-PAX leadership team made a first estimate of importance weighting, then presented their assessment to the PACE Science and Applications Team (SAT) in late 2021 / early 2022. Based on that feedback, the weighting was significantly refined, and some measurement objective categories were added. Figure 1 is a summary of that weighting by validation objective category, while Table 7 describes specific weighting broken down by measurement objective. Weighting is distributed roughly evenly across the objectives, with the most priority given to validating new retrieval properties (objective 1).

Figure 1 Validation Traceability Matrix (VTM) objective weighting



3.4 Geophysical parameters

These are the individual parameters to be measured or retrieved (Decadal Survey for Earth Observation, NAS 2017), comprising each category of measurement objectives, including parameters of physical, chemical, geological, or biological origin. For example, aerosol optical depth (AOD).

3.5 Instruments

These are the instruments capable of observing a geophysical parameter, such as an airborne multi-angle polarimeter. This can either be a direct, remote or proxy validation instrument (described below), and identified as such in the next category. The VTM describes the type of instrument, but not an individual instrument if multiple options exist. Furthermore, the VTM may list several types of instrument options, only one of which is needed unless otherwise noted.

3.6 Instrument type

Direct, *Remote*, and *Proxy* validation refers to different categories of instrumentation. *Direct* instruments measure the targeted geophysical property *in situ*. For example, a Cloud Droplet Probe (CDP, e.g., Faber et al., 2018) measures the liquid cloud droplet size distribution from the wing of an aircraft and represents that geophysical parameter in that discrete time and place. *Remote* (sensing) instruments may be deployed within the observed scene, but remotely assess geophysical parameters by interpreting how they interact with that scene, such as by scattering sunlight. The geophysical parameter determined from a remote instrument may represent a different physical location than a direct measurement. *Proxy* instruments are a subset of remote sensing instruments, but have characteristics similar to an instrument on PACE, and employ similar algorithms. The AirHARP and SPEX Airborne instruments (McBride et al., 2020, Puthukkudy et al., 2020, Smit et al, 2019a,b) are examples of PACE proxies for the HARP2 and SPEXone instruments, respectively.
Table 5 describes and contrasts these types. The choice of which instrument type is most appropriate to satisfy a measurement objective depends on the characteristics of that objective. In most cases it is preferable to have a proxy and either remote or direct instruments available. In situations where this is not possible, proxy measurements may suffice.

Table 5 Instrument measurement types

Instrument type definition	
Proxy	Proxy validation is the use of airborne remote sensing instruments similar to those on PACE, utilizing the same or very similar retrieval algorithms.
Remote	Remotely sensed validation uses retrievals of validation parameters from instruments dissimilar to those on PACE.
Direct	Direct validation is the use of *in situ* sampling of atmospheric, ocean or land parameters.

3.7 Instrument requirements

These are general deployment needs for the instrument, such as aircraft host. In this case, aircraft capabilities are categorized as three broad types, described in Table 6. For instruments not deployed in aircraft, requirements define the ground site needs, research ship capabilities, etc.

Table 6 Aircraft categories

Aircraft categories	
Type A	High altitude, sufficient to overfly aerosols and clouds, e.g., ER-2, WB-57
Type B	Large payload mid-altitude aircraft, e.g., P-3, DC-8. Includes ability to determine if aerosols or clouds are above current flight path, and capability to fly above if needed.
Type C	Small payload low to mid-altitude aircraft, e.g., B-200, Twin Otter

3.8 Mission requirements

These are the physical conditions and other needs for successful validation, such as weather conditions. These fall into a variety of categories, which may or may not be defined based upon the objectives and measurements.

3.8.1 Mission requirements – Surface

The nature of the ocean or land surface in the observed scene.

3.8.2 Mission requirements – Aerosol

Aerosol conditions in the observed scene.

3.8.3 Mission requirements – Cloud

Cloud conditions in the observed scene.

3.8.4 Mission requirements – Other instrumentation

In some cases, measurement requirements require concurrent observation by multiple instruments. For example, if an airborne proxy instrument type is listed in this row, a corresponding ground-based measurement that is desired would be listed here.

3.8.5 Mission requirements – Satellite

If coordinated observations with satellite overflight is desired, those requirements are listed here. This is sometimes the case for direct or remote instrument measurement types.

3.8.6 Mission requirements – Platform

This requirement refers to the circumstances of the instrument hosting platform. For example, and airborne proxy instrument may require observation in a specific solar geometry, or assurance that cirrus clouds are not present above the aircraft.

3.8.7 Mission requirements – Observation time

The length of time required for a 'successful' observation. For airborne field campaigns, this refers to flight hours, including transit time to and from the observation target region, and is deployment region specific. This is a parameter that feeds into a detection probability function (*b(t)*, where *t* refers to time) under the principles of Bayesian optimal search theory (Stone, 1989), which we adapt to the assessment of field campaign plans (Section 4), previous field missions (Section 5) and in support of planning during an ongoing field campaign (Section 8). We will use the exponential detection function, *b(t)*,

$$b(t) = 1 - e^{-\frac{t}{h}} \tag{1}$$

where *h* is the observation time. This function describes a case where the probability of successful observation is zero at *t=0*, roughly 63% at *t=h*, and asymptotically approaches 100% as *t* increases (it is 95% for 3*h*). There are other possible detection functions, but in addition to being physically realistic, this has the advantage of a simple derivative, which will be used in Section 8.

Note: this field is not currently specified in the PACE-PAX VTM but will be determined as specific flight plans are developed.

3.8.8 Mission requirements – Other

Other requirements not previously mentioned.

The full PACE VTM, including desired capabilities and what is to be achieved with PACE-PAX, is available here: https://pace.oceansciences.org/campaigns.htm

Table 7 Validation Traceability Matrix (VTM) summary, where value of *w* (importance of parameter in reaching the validation objective) increases with importance. Sum value of the objectives is 123.

Validation objectives	ID	Measurement objectives	Importance, w	Objective total
1. Validate new retrieval properties	**A**	Land surface parameters	2	35
	B	Ocean radiometric parameters	2	
	C	Aerosol parameters over the ocean	10	
	D	Aerosol parameters over land	10	
	E	Cloud parameters	10	
	F	Ocean surface parameters	1	

2. Assess spatial and temporal scale impact on validation	**A**	Cloud parameters	8	16
	B	Aerosol parameters	8	
3. Validate in a narrow swath	**A**	Aerosol parameters over the ocean	10	25
	B	Aerosol parameters over land	10	
	C	Cloud parameters	5	
4. Validate radiometric and polarimetric properties	**A**	Validate large reflectances	3	12
	B	Validate large reflectances with high polarization	3	
	C	Validate large reflectances with low polarization	3	
	D	Overfly vicarious calibration sites	3	
5. Target specific geometries, season, and time of day	**A**	Aerosol over ocean retrieval geometry dependence	2	6
	B	Aerosol over land retrieval geometry dependence	2	
	C	Cloud property retrieval geometry dependence	2	
6. Focus on specific processes or phenomena	**A**	High aerosol loads over land	4	29
	B	High aerosol loads over ocean	4	
	C	Multiple aerosol layers	1	
	D	Aerosol under thin cirrus	2	
	E	Aerosol above liquid phase cloud	4	
	F	Broken clouds with complex structure	4	
	G	Dust aerosols over ocean	1	
	H	Aerosol and ocean parameters over turbid waters	2	
	I	Aerosol and ocean parameters over biologically productive waters	5	
	J	Aerosol and ocean parameters with and without reflected sunglint	1	
	K	Smoke aerosols over ocean	1	

4 VALIDATION PLAN EVALUATION

The VTM is a necessarily complex document. But it can be a useful tool for the implementation of a validation field campaign, assessment of prior campaigns, or can inform day to day operation during an ongoing campaign (by guiding flight planning, for example). To do so, we have adapted elements of Bayesian search-and-rescue theory (Stone, 1989). Rather than assessing the likelihood of finding a distressed ship in a grid of geographic locations, we assess the likelihood of meeting a set of measurement objectives.

We have defined several metrics to help assess the relative merits of implementation plans, for which specific instruments and deployment scenarios have been selected. These metrics incorporate the design of the VTM and subjective assessments of the relative importance of those design elements, the capacity of a specific field campaign to satisfy them, and the ability to meet mission requirements.

"Validation instrument potential", *V* [unitless], expresses the ability of the set of instruments in a given field campaign plan to address measurement objectives, independent of mission length. It incorporates two subjective assessments:

a) the weight assigned to each measurement objective (*w,* defined as importance in the VTM), and
b) the completeness to which the chosen instrumentation can make the required measurements (*c*, unitless and between 0 for no ability and 1 for perfect ability). Some instrument choices may be a less than perfect match to the VTM requirements. For example, a chosen instrument may not have a required spectral channel or may not be deployable in all the required conditions. In such cases, *c* is assigned a subjective assessment value between 0 and 1.

In this manner we can prioritize instruments of varying capability. *V* is thus simply defined:

$$V = \frac{\sum_{i=1}^{n} w_i c_i}{\sum_{i=1}^{n} w_i} \tag{2}$$

where *n* is the number of measurement objectives, and *i* is an index to each. *V* can have values between 0 and 1, where the latter indicates a perfect instrument potential. This metric can be considered instantaneous and does not incorporate deployment considerations such as location and available time.

V is useful to evaluate different instrument configurations, but a full assessment also requires knowledge of the detection probability function, *b(t)*, defined in equation 1, and *p,* the probability of encountering favorable measurement conditions, which incorporates knowledge of weather climatology and other matters pertaining to success.

Our detection probability function is thus updated to

$$b_i^*(t) = 1 - e^{-\frac{tp_i}{h_i}} \tag{3}$$

where the probably of favorable measurement conditions (*p*) has been incorporated for each of the specific measurement objectives (index of i). Furthermore, an overall field campaign assessment needs to include our measurement objective weights (*w*), but relative to the total of all validation plan objective weights (n, indexed by j). To this end, we define a relative weighting, *z*:

$$z_i = \frac{w_i}{\sum_{j=1}^{n} w_j} \tag{4}$$

Finally, we define the time dependent field campaign success, which we call the success function, *S(t)*.

$$S(t) = \sum_{i=1}^{n} c_i \, z_i b_i^*(t) = \sum_{i=1}^{n} c_i \left[\frac{w_i}{\sum_{j=1}^{n} w_j}\right]\left(1 - e^{-\frac{tp_i}{h_i}}\right) \tag{5}$$

This function incorporates our measurement objective weights, *w*, the completeness with which a given instrument configuration meets those objectives, *c*, the amount of time required to make a measurement, *h*, and the probability that favorable conditions exist at a given time during the field campaign, *p.* It is important to note that, with the exponential detection function we have defined, $S(t) = V$ as t approaches infinity (instrument capabilities at maximum measurement time). It is also possible to augment the success function with distribution functions of probability (probably most feasible for *p*), in which case *S* would represent the probability distribution of success as a function of time.

Table 8 Validation assessment metrics for theoretical field campaign Alpha. V=0.78

Measurement objective	Measurement objective weight, *w*	Observation time required, *h*	Measurement completeness, *c*	Probability of success, *p*
A	4	20	1.0	0.5
B	2	10	1.0	0.5
C	2	15	0.0	0.1
D	1	5	1.0	0.1

Table 9 Validation assessment metrics for theoretical field campaign Beta. V=0.75

Measurement objective	Measurement objective weight, *w*	Observation time required, *h*	Measurement completeness, *c*	Probability of success, *p*
A	4	20	0.75	0.75
B	2	10	0.75	0.75
C	2	15	0.75	0.2
D	1	5	0.75	0.2

Table 10 Validation assessment metrics for theoretical field campaign Gamma. V=0.5

Measurement objective	Measurement objective weight, *w*	Observation time required, *h*	Measurement completeness, *c*	Probability of success, *p*
A	4	20	0.25	0.9
B	2	10	0.25	0.9
C	2	15	1.0	0.95
D	1	5	1.0	0.75

To illustrate the value of this function, we compare three field campaign configurations described in Table 8 (field campaign 'Alpha'), Table 9 (field campaign 'Beta'), and Table 10 (field campaign 'Gamma'. All have identical measurement objectives, weights assigned to those objectives (***w)***, and requirements on observation time (*h*), but instrumentation used has different capabilities allowing for measurement completeness (*c*). The Alpha field campaign makes complete measurements for three of the four objectives, while the Beta field campaign makes slightly incomplete measurements for all four but has a slightly higher probability of success. Gamma has a clearly deficient capability for the most important objective and for one of the moderately important objectives, but a much higher probability of success.

We choose these configurations to illustrate the interplay between different choices possible in a field campaign. Alpha and Beta have very similar values of validation instrument potential (V), but different success functions, as shown in Figure 2. The steeper initial slope for Gamma (purple) indicates that it may be a viable strategy for field campaigns with shorter available time but is limited in its ability to fully meet mission success. The higher asymptote for Alpha (red) and Beta (green) indicates that they are a better choice with greater time resources. We would also like to note that time, t, is not the same as the flight hours needed for a field campaign, since the success function presumes all measurements are made simultaneously, among other factors. Instead, this function should be used as a mission comparison tool. Section 8 is a more detailed guide for flight planning underway field campaigns.

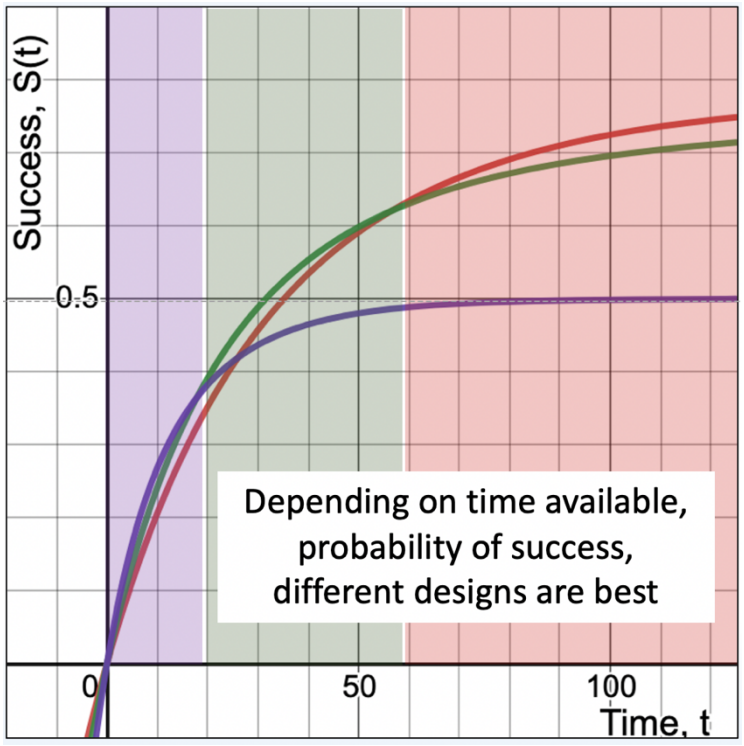


Figure 2 Success functions (equation 5) for field campaign Alpha (red), Beta (green), and Gamma (purple).

These example field campaigns are of course much simpler than our VTM, but they demonstrate how the V and $S(t)$ can be used to aid configuration and deployment choices. As mentioned previously, the metrics are only as good as the subjective assessments that go into them. Their value is in how they reduce the complex, multi-parameter, subjective choices needed for designing a field campaign into combinations of simple assessments.

5 ASSESSMENT OF PREVIOUS FIELD MISSIONS

5.1 Scoring mechanism

We use the validation instrument potential, V (defined in equation 2), as a means to assess previous field campaigns in their ability to meet the measurement objectives as described in our VTM. In this case, measurement completeness, c, describes the actual success in making the measurements required for an objective. Deployed instrumentation for a given field campaign are compared to the VTM and scored in terms of this completeness and the weights of the associated measurement objectives, to determine V. In this way, we can understand how the configuration of previous field missions, designed for other purposes, could serve the needs of a PACE validation field campaign.

We use the following scoring to assess previous field missions. Objectives are judged at the measurement objective level. Those for which measurements were made, and data were used for that objective, are assigned a (maximum) score of 1. A score of 0.75 is assigned to objectives for

which measurements were made but the data have not yet been assessed. Lower scores are assigned to measurements that are incomplete or had unfavorable conditions (or both).

5.2 ACEPOL

The Aerosol Characterization from Polarimeter and Lidar (ACEPOL) airborne field campaign was conducted from the NASA Armstrong Flight Research Center (AFRC) in Southern California in the fall of 2017 (Knobelspiesse et al., 2020). The high-altitude ER-2 aircraft carried six instruments: four multi-angle polarimeters (AirMSPI, RSP, AirHARP and SPEX Airborne, the latter two of which are airborne proxies of PACE instruments) and two lidars (CPL and HSRL-2). Flights were performed over a variety of conditions, coordinated with ground-based instrumentation (AERONET, AERONET-OC, a ground characterization team at Rosamond Dry Lake, etc.).

ACEPOL was conducted as part of the Aerosol-Cloud-Ecosystems (ACE) mission study (da Silva et al., 2020), and also received funding from the Netherlands Institute for Space Research (SRON) and Cloud-Aerosol Lidar and Infrared Pathfinder Satellite Observations (CALIPSO, Winker et al., 2009) Mission for instrument development and validation. ACEPOL differed from field campaigns with narrow, scientific, objectives: it structured to observe a wide variety of conditions, which were prioritized with the use of a 'scorecard' similar to our VTM.

Our assessment of the Validation Instrument Potential, *V*, for ACEPOL is 0.555.

In many ways, the ACEPOL field campaign contains many of the components of a successful PACE validation field campaign. It deployed two PACE polarimeter proxies and had a complement of two different lidars on board a high-altitude aircraft. It flew in a wide variety of conditions over land and ocean and included coordinated observation with ground sites and satellite overflight. The following were some of the most important missing elements, with potential increases in *V* had they been included.

1. An appropriate UV-SWIR imager to act as a PACE OCI proxy. Gao et al., (2020) approximated this proxy by combining data from the RSP multi-angle polarimeter (which has SWIR channels) with the SPEX Airborne (which is hyperspectral in the VIS), but UV measurements were not available ($V + 0.026$).
2. More complete ground measurements of Remote Sensing Reflectance. A single AERONET-OC instrument site was available for this purpose ($V + 0.045$).
3. More observations with moderate to high aerosol optical depth. Surprisingly for this part of the world and season, there were few forest fires and minimal air pollution in both the California Central Valley and Los Angeles basin during the period of ACEPOL. To compensate, targets were found farther afield, requiring additional flight hours ($V + 0.098$).
4. More observations with liquid phase clouds, especially marine stratocumulus clouds ($V + 0.173$).
5. Add an additional platform making in situ aerosol and cloud sampling measurements ($V + 0.157$).

Adding all of the above elements to ACEPOL would result in an increase of V+0.372, for a total of 0.927 – nearly complete for the purposes of PACE validation.

To illustrate the use of V, we also tested the impact of elimination of the lidars onboard the aircraft during ACEPOL. This served to decrease the V by 0.066. However, it is important to note that the impact of this descope (and the enhancements describe above) are affected by other conditions. For example, ACEPOL was not able to observe high aerosol loads over the ocean or multiple aerosol layers. Had those observations been made, the lidar descope would have had a larger impact.

Generally speaking, ACEPOL was a successful field campaign for its purposes, and also served as a resource for PACE pre-launch algorithm development and testing. Examples of research using ACEPOL data for instrument and algorithm development relevant to PACE include Gao et al, 2020, 2021, Hannadige et al, 2021, Fu et al., 2019, Martins et al., 2018, McBride et al, 2020, Puthukkudy et al, 2020, Smit et al., 2019a, b.

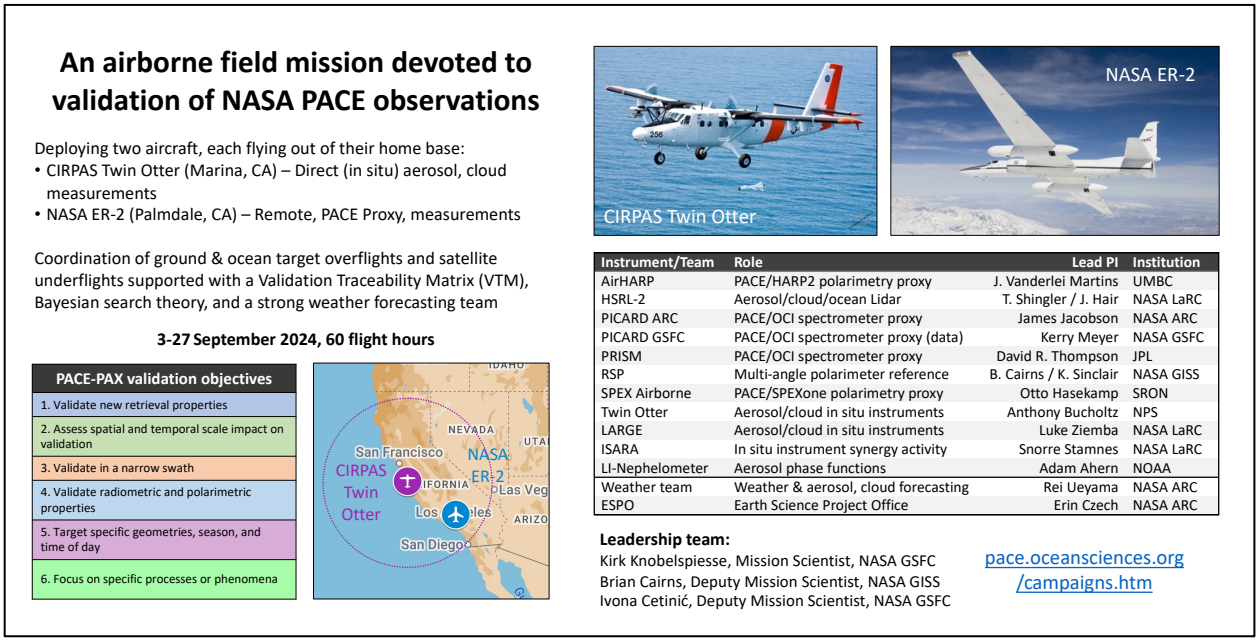
However, the analysis here indicates that ACEPOL did not meet all the objectives of PACE validation (had it occurred at the same time as the PACE mission observations). Starting from the ACEPOL design, the five additions mentioned above were incorporated into the plan for PACE-PAX. This is described in subsequent sections.

6 PACE-PAX CAMPAIGN IMPLEMENTATION

6.1 Overview

After vetting by the PACE Project Science and Science and Applications Teams, the VTM was used to create the PACE-PAX campaign plan. Summarized in Figure 3, PACE-PAX will consist of roughly four weeks of flights in September of 2024 by a pair of aircraft. The NASA ER-2, based at the NASA Armstrong Flight Research Center (AFRC) in Palmdale, CA, will carry a payload of remote and PACE proxy instruments. The Center for Interdisciplinary Remotely Piloted Aircraft Studies (CIRPAS) Twin Otter, based at the Marina Municipal Airport in Marina, CA, will fly a suite of direct (in situ) instruments. Although operating out of at different locations, the extensive range of the high-altitude ER-2 aircraft enables coordination with the Twin Otter as they overfly targets at the surface or underfly the PACE spacecraft. The PACE-PAX weather forecasting team will guide flight planning to be performed by the leadership team, who will use the Bayesian search theory described in previous sections and Section 8 to achieve an optimal satisfaction of the VTM. The remainder of this section describes the details of the PACE-PAX campaign implementation.

Figure 3 PACE-PAX campaign plan. For a full list of airborne instruments, see Tables 12-15 and Section 13.



6.2 Management approach

The PACE-PAX mission will require a dedicated team for successful planning and implementation. Overall, PACE Project Science will lead the mission in collaboration with the PACE Program Scientists at NASA HQ and will select one of its members to lead as the Mission Scientist (MS), described below. Once the planning stage of PACE-PAX has begun, regularly scheduled meetings will occur among the leadership team, with NASA HQ, and among the entire PACE-PAX team (in descending order of frequency).

The PACE-PAX team will include the following members.

PACE-PAX mission scientist (MS):
Kirk Knobelspiesse, NASA GSFC Code 616, will have an overall responsibility for the field campaign, will lead the PACE-PAX team, and will be the interface between the team and PACE Project Science, NASA HQ, the PACE Validation Science Team (to be competed and funded separately), and others. They will be responsible for defining and meeting the validation objectives, their scope, and implementation.

PACE-PAX deputy mission scientist(s) (DMS):
Brian Cairns, NASA GSFC Code 611 (GISS) will assist the PACE-PAX mission scientist and serve in their place when the MS is unavailable for meetings or other activities. He will oversee the in-situ aircraft component (the CIRPAS Twin Otter), including the selection of instruments and management of deployment and other activities.

Ivona Cetinić, NASA GSFC Code 616 / Morgan State University will assist the PACE-PAX mission scientist and serve in their place when the MS is unavailable for meetings or other activities. Her responsibilities include oversight of documentation, such as the PACE-PAX white

paper. She will also serve as a liaison to PACE validation efforts beyond those covered by PACE-PAX, and to the general Ocean Biogeochemistry community. She will also serve a similar role to the yet to be competed PACE Validation Science team.

PACE-PAX project manager(s) (PM): The NASA Ames Earth Science Project Office (ESPO), represented by Erin Czech (NASA ARC) will provide program management guidance. He and his team will work with the aircraft managers, instrument scientists and other members of the team regarding shipping, deployment of personnel, and other matters pertaining to logistics. They will set the set and maintain the budget and schedule, and work with the Aircraft Manager(s) to ensure risk management and safety.

PACE-PAX instrument scientists (IS): are responsible for integration, deployment, and operations for individual scientific instruments, as well as the timely data delivery of observables (Table 11).

PACE-PAX Aircraft Manager(s) (AM):
Franzeska Becker (NASA AFRC) and Samuel Choi (NASA AFRC) will serve as the point of contact between the PACE-PAX team and the ER-2 aircraft personnel, including responsibility for instrument integration, planning, and operations.

Anthony Bucholtz (Naval Postgraduate School) will serve as the point contact between PACE-PAX team and the CIRPAS Twin Otter aircraft personnel, including responsibility for instrument integration, planning, and operations.

Table 11. List of PACE-PAX instrument scientists.

INSTRUMENT	LEAD PI	INSTITUTION
AirHARP	J. Vanderlei Martins	University of Maryland, Baltimore County
HSRL-2	Taylor Shingler / Jonathan Hair	NASA Langley Research Center
PICARD ARC	James Jacobson	NASA Ames Research Center
PICARD GSFC	Kerry Meyer	NASA Goddard Space Flight Center
PRISM	David R. Thompson	NASA Jet Propulsion Laboratory
RSP	Brian Cairns / Ken Sinclair	NASA Goddard Institute for Space Studies
SPEX Airborne	Otto Hasekamp	SRON Netherlands Institute for Space Research
LARGE	Luke Ziemba	NASA Langley Research Center
ISARA	Snorre Stamnes	NASA Langley Research Center
Pol-Nephelometer	Adam Ahern	NOAA Chemical Sciences Laboratory

PACE-PAX weather forecasting team (WF):
The NASA Ames Research Center (ARC) forecasting group, PI lead Rei Ueyama, will provide meteorological and aerosol forecasting support during planning and operations of PACE-PAX, including climatology study, developing mission specific forecast products, supporting the dry-run exercise, and provide onsite support during the campaign.

PACE-PAX data manager (DM):
Inia Soto Ramos (NASA GSFC Code 616 / Morgan State University) and Chris Proctor (NASA GSFC Code 616 / SSAI) will ensure that data collected during the campaign will be archived in accordance with NASA policies in the identified repository.

6.3 The PACE-PAX setting

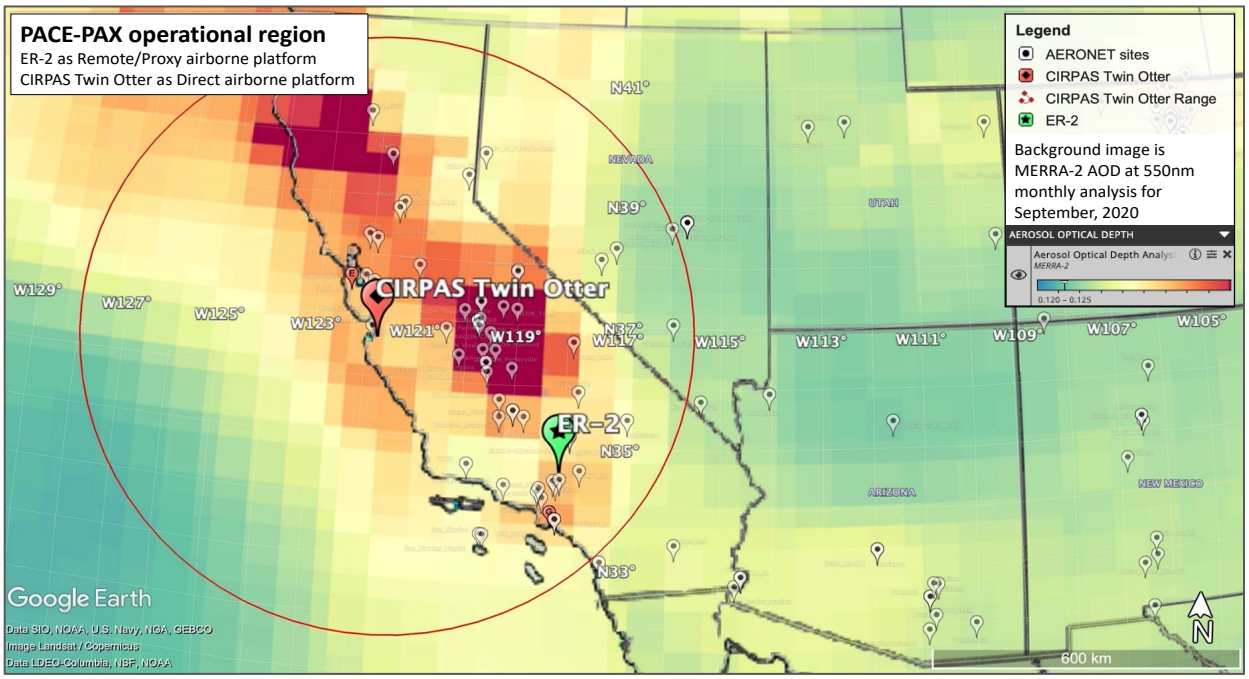


Figure 4. Preliminary map of the PACE-PAX operations area. Red circle depicts range of CIRPAS Twin Otter, centered on Marina, CA. The ER-2 aircraft is based at the Armstrong Flight Research Center (AFRC) noted in green. The ER-2 range extends beyond the map. Map overlay is the MERRA-2 AOD 555nm for September 2020 (image made in Google Earth).

In order to satisfy validation objectives (see Section 3.1), measurement objectives (see Section 3.2), and still abide by organizational constrains (e.g. aircraft availability, budget limitations), PACE-PAX will be September 3-27, 2024, in the central California region (see Figure 2). California was chosen in part because it is the home for the two aircraft. The primary reason, however, is the diversity of aerosol, cloud, ocean and land surface conditions within operational range, the availability of surface networks of instruments (e.g. AERONET), and the potential for overflights of oceanographic research cruises operating out of the West coast of the United States.

The timing of the campaign sets it within the range of mission requirements of field work to be within '*12 months of commissioning'* (for a PACE launch in January, 2024, as per PACE PLRA and MRD, see Section 1.4), while operating in the most likely seasonal period to encounter ideal conditions. A weakness of the ACEPOL field campaign timing (October of 2017) was that very few moderate and high aerosol loads were encountered within the considerable range of the ER-2 aircraft operating out of NASA AFRC. PACE-PAX will happen earlier (September) and within the fire season of the Western United States. As an example, the overlay in Figure 4 is the Modern-Era Retrospective analysis for Research and Applications (MERRA-2) monthly reanalysis of aerosol optical depth (AOD) in September 2020, indicating extremely high aerosol loads in coastal areas and the California Central Valley. The latter is particularly well instrumented with AERONET and air quality sites. Additionally, September is the period of breakup of the marine stratocumulus cloud deck associated with the California Current in the Pacific Ocean. This provides for the use of stratocumulus clouds for PACE-PAX validation purposes (e.g. objectives 1e, 2a, 3c, 5c, 6e, see Table 7) in some regions, while also the ability to observe the ocean in cloud free conditions (e.g. objectives 1b, 1c, 1f, 3a, 4b, 5a, 6b, 6g, 6h, 6i, 6j, 6k) in others. Sixty flight

hours are planned for each aircraft, corresponding to 7-10 flights by the ER-2, and similar or more from the Twin Otter. Many of the validation objectives can be satisfied simultaneously if conditions permit (e.g. a coordinated Twin Otter, ER-2 and PACE underflight track of moderate load smoke aerosols over the coastal ocean would satisfy objectives 1b, 1d, 2b, 3a, 5a, 6h, 6i, 6k). This quantity of flight hours should enable multiple attempts at meeting all 29 validation objectives.

The PACE-PAX setting has also been selected to minimize costs. As previously noted, both aircraft will operate out of their home base, which reduces travel and deployment costs for aircraft management, pilots, and mechanics. Furthermore, the California location is close to home for several of the instrument teams, and a familiar operating territory for all teams. Selection priority was given to instruments that have already been integrated on the intended aircraft, and only essential engineering development efforts are included.

6.4 Airborne platforms

NASA owns and operates a variety of aircraft that can be used for earth science, some of which are managed by the Airborne Science Program (ASP, https://airbornescience.nasa.gov). During the planning of the PACE-PAX aircraft from other government agencies and institutions (NOAA, DoD, NSF) were also considered. While taking into consideration the targeted area of PACE-PAX, feasibility of instrument integration, availability of aircraft, as well as targeted observables outlined in the VTM, two were chosen: the NASA ER-2 (for Remote and Proxy measurements) and the CIRPAS Twin Otter (Direct measurements).

Direct measurements can be performed from the same airborne platform as Proxy/Remote measurements, but specific maneuvers must be made in order to satisfy one or the other objectives, and they cannot occur at the same time. This has been done before (e.g. the second two deployments of the ObseRvations of Aerosols above CLouds and their intEractionS (ORACLES) field campaign (Redemann et al., 2021, see Figure 12 for aircraft maneuvers), however it prolongs the operations (longer flight-days) and adds a temporal lag between Proxy and Direct measurements. Alternatively, Direct and Proxy/Remote observations can be made simultaneously with separate platforms. While the use of multiple aircraft can mean higher costs, the selected aircraft can be well suited for their respective roles and use flight hours more efficiently. The Imaging Polarimetric Assessment and Characterization of Tropospheric Particulate Matter (ImPACT-PM, Kalashnikova et al., 2018) is an example of this approach that may be a (smaller scale) model for PACE-PAX. The purpose of that campaign was to validate AirMSPI retrieval capability of smoke aerosol properties in preparation for the launch of the Multi-Angle Imager for Aerosols (MAIA, Diner et al., 2018) instrument. AirMSPI, serving as a proxy for the MAIA instrument, was deployed on the high-altitude ER-2 aircraft from ARFC. It overflew the US Naval Postgraduate School's (NPS) Center for Interdisciplinary Remotely Piloted Aircraft Studies (CIRPAS) Twin Otter, outfitted with aerosol and cloud direct sampling instrumentation. The CIRPAS Twin Otter, deployed from Marina, CA, made coordinated observations with the ER-2 of smoke plumes in central California.

PACE-PAX will have similarities with the ImPACT-PM campaign. The ER-2 is a T*ype A* aircraft, managed by NASA Headquarters Airborne Science Program and operated by Armstrong Flight Research Center (AFRC) in Palmdale, CA, that is capable of long-range (5,000 nm), long

endurance (12 hours), high-altitude flights (max 70,000 ft). As discussed previously, instrumentation deployed aboard the ER-2 will serve as a Proxy for PACE measurements both from OCI and MAPs, while other instruments will serve Remote validation needs, conforming to the requirements of the VTM (Figure 4). Direct measurements of aerosols and clouds will be done from the CIRPAS Twin Otter aircraft. Its flight capabilities (18,000 ft max altitude, 300 nm range, and 5 hours of max flight time) make it a *Type C* aircraft an ideal choice for collection of the direct measurements. In addition, this aircraft has a suite of facility instruments that support the needs of this campaign, in addition to the capability to host additional instrumentation (e.g., a well characterized air sampling inlet, with delivery into the cabin, and additional instrument ports (zenith and nadir)).

6.5 Direct measurements of aerosols and clouds

Measurements of cloud and aerosol properties can be made by sampling from an aircraft flying through a cloud or aerosol plume. Airborne 'Direct' measurements are identified in many parts of the VTM (see Section 3.6), and they are also necessary to for comparison to 'Proxy' measurements when there is no satellite overflight or ground based Direct measurements to compare to.

The CIRPAS Twin Otter aircraft will be outfitted with a variety of instruments that measure aerosol and cloud properties, as described in Table 12. Some instruments are designated 'Facility' and are regularly deployed on the Twin Otter. The Twin Otter team is responsible for delivery of data from those instruments. In addition to the Facility instruments, the Langley Aerosol Research Group (LARGE) suite will include several other instruments, and NOAA will provide a Laser imaging nephelometer (Ahern et al., 2022). The challenge of Direct validation is to measure parameters that are comparable to PACE products. No single instrument can do this, so the set of measurements that will be made on the Twin Otter have been selected to, for example, span the particle size range, account for the impacts of humidification or drying on aerosols, and so forth. As part of this effort, a separate set of LARGE instruments will be deployed to the Marina Airport, so that measurement comparisons in ambient conditions can be made prior and after a Twin Otter flight and assess inlet performance.

An important aspect in the use of Twin Otter measurements for Direct validation will be the methods used to combine data into validation relevant measurements. The In-Situ Aerosol Retrieval Algorithm (ISARA), developed by a team at NASA LaRC, will be modified for the needs of PACE-PAX. ISARA has been successfully used previously as part of the CAMP2Ex (https://espo.nasa.gov/camp2ex/content/CAMP2Ex) and ACTIVATE (https://activate.larc.nasa.gov/) airborne campaigns. Similarly to PACE-PAX, these campaigns flew a complex suite of in-situ instruments on the CIRPAS Twin Otter.

Table 12 CIRPAS Twin Otter instrumentation setup for PACE-PAX, its targeted parameters, and validation objectives these parameters satisfy. This table contains facility instruments (no highlight), and add-on instrumentation (highlighted in gray).

Instrument	Type	Observed geophysical parameters	Validation Objective
Navigation	Facility	Position, attitude, airspeed, etc.	n/a
Meteorology	Facility	Temperature, pressure, dew point	n/a
Wind	Facility	Wind speed and direction, vertical winds	n/a

Ultra-Fine 3025A particle counter	Facility inlet instrument	Condensation Particle Counts (CPC) > 3nm	1e, 2a, 3c, 5c, 6e, 6f
Magic200 CPC particle counter	Facility inlet instrument	Condensation Particle Counts (CPC) ~5nm – 2.5µm	1e, 2a, 3c, 5c, 6e, 6f
TSI Scattering Nephelometer	Facility inlet instrument	Dry aerosol scattering coefficient at 450, 550, 700nm	1c, 1d, 2b, 3a, 3b, 5a, 5b, 6a, 6b, 6c, 6d, 6e, 6g, 6h, 6i, 6j, 6k
Particle soot absorption photometer (PSAP)	Facility inlet instrument	Aerosol absorption coefficient at 467, 530, 660nm	1c, 1d, 2b, 3a, 3b, 5a, 5b, 6a, 6b, 6c, 6d, 6e, 6g, 6h, 6i, 6j, 6k
PMS PCASP	Facility ambient wing probe	Aerosol fine mode size distribution, 0.1-3µm (heated)	1c, 1d, 2b, 3a, 3b, 5a, 5b, 6a, 6b, 6c, 6d, 6e, 6g, 6h, 6i, 6j, 6k
DMT Cloud Imaging Probe (CIP)	Facility ambient wing probe	Cloud particle size, 25 µm – 1.55 mm (with 25-µm resolution)	1e, 2a, 3c, 5c, 6e, 6f
DMT Cloud and Aerosol Spectrometer (CAS)	Facility ambient wing probe	Cloud and Aerosol particle size, $Range_0$: 0.6 µm to 50 µm; $Range_1$: 0.3 to 28.5 µm with 10, 20, 30, or 40 size bins	1c, 1d, 1e, 2a, 2b, 3a, 3b, 3c, 5a, 5b, 5c, 6a, 6b, 6c, 6d, 6e, 6f, 6g, 6h, 6i, 6j, 6k
DMT Hotwire Liquid Water Content (LWC)	Facility ambient wing probe	Liquid water content 0.01 – 3 g/m^3	n/a
DMT Ultra-High Sensitivity Aerosol Spectrometer	LARGE suite inlet instrument	Dry aerosol size distribution, 0.06-1µm	1c, 1d, 2b, 3a, 3b, 5a, 5b, 6a, 6b, 6c, 6d, 6e, 6g, 6h, 6i, 6j, 6k
TSI-3321 Aerodynamic Particle Sizer (APS)	LARGE suite inlet instrument	Dry aerosol size distribution, 0.5-5µm	1c, 1d, 2b, 3a, 3b, 5a, 5b, 6a, 6b, 6c, 6d, 6e, 6g, 6h, 6i, 6j, 6k
TSI-3563 Scattering Nephelometer, Dry	LARGE suite inlet instrument	Dry aerosol scattering coefficient (RH<40%), 450, 550, 700nm	1c, 1d, 2b, 3a, 3b, 5a, 5b, 6a, 6b, 6c, 6d, 6e, 6g, 6h, 6i, 6j, 6k
TSI-3563 Scattering Nephelometer, Humidified	LARGE suite inlet instrument	Aerosol scattering coefficient at RH=80%, 450, 550, 700nm	1c, 1d, 2b, 3a, 3b, 5a, 5b, 6a, 6b, 6c, 6d, 6e, 6g, 6h, 6i, 6j, 6k
Aerodyne CAPS-PM_{SSA} at RH < 40%	LARGE suite inlet instrument	Total aerosol dry extinction coefficient and single scattering albedo at 530nm	1c, 1d, 2b, 3a, 3b, 5a, 5b, 6a, 6b, 6c, 6d, 6e, 6g, 6h, 6i, 6j, 6k
Laser Imaging Nephelometer (LiNeph)	NOAA inlet instrument	Aerosol phase function and polarized phase function at 405 and 660nm	1c, 1d, 2b, 3a, 3b, 5a, 5b, 6a, 6b, 6c, 6d, 6e, 6g, 6h, 6i, 6j, 6k

6.6 Proxy and Remote measurements

For PACE-PAX, suite of Proxy and Remote measurements will be made by instrumentations deployed aboard an ER-2 aircraft. The ER-2 is a *Type A* aircraft, managed by NASA Headquarters Airborne Science Program and operated by Armstrong Flight Research Center (AFRC) in Palmdale, CA, that is capable of long-range (5,000 nm), long endurance (12 hours), high-altitude flights (max 70,000 ft). As discussed previously, instrumentation deployed aboard the ER-2 will serve as a Proxy for PACE measurements both from OCI and MAPs, conforming to the needs of the VTM.

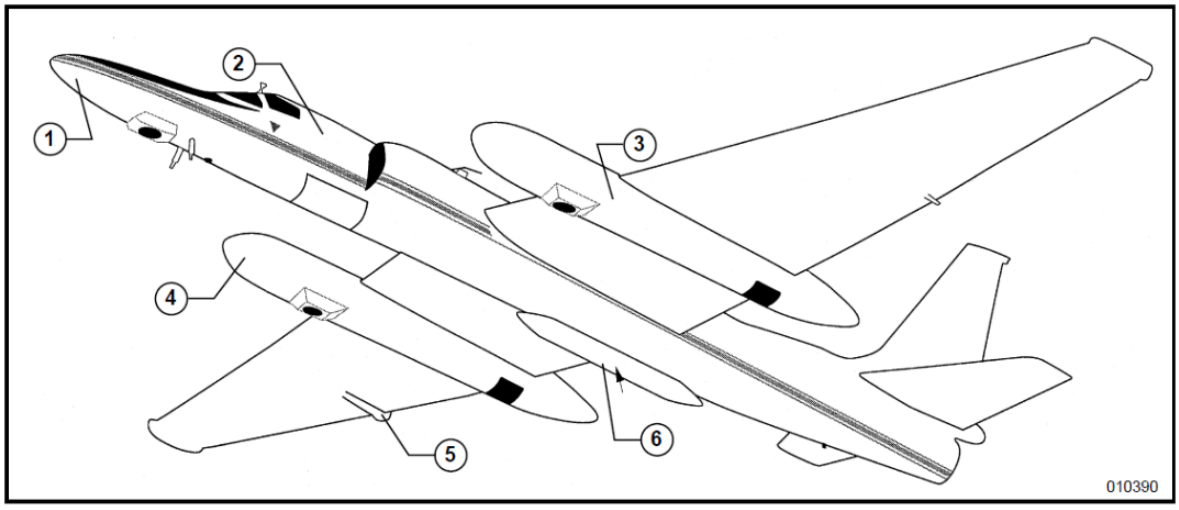

Figure 5. Potential layout for the instruments aboard ER-2: 1 – PRISM, 2 – HSRL-2, 3 – PICARD (fore) + SPEX Airbone (aft), 4 – AirHARP (fore) + RSP (aft). Area 5 and 6 are unused. For instruments description see Section 6.6. Note wing pod locations (3 and 4) of instruments may be reconfigured as mass balance and other issues are determined in preparation for the campaign.

6.6.1 ER-2 Airborne UV-SWIR spectrometers: PRISM and PICARD

Identifying a UV-SWIR spectrometer that can act as a proxy for the OCI instrument is a challenging task: it must match the UV-NIR hyperspectral capability and discrete SWIR channels while maintaining a high signal-to-noise (SNR) ratio appropriate for observations of a relatively dark ocean (see Table 1). For background, we describe several potential OCI proxies in detail, acknowledging that there are other potential proxy instruments available as well. With that in mind, two instruments have been selected to cover the wide range of requirements, primarily the spectral breath of the OCI, and individual science components of the mission – ocean, clouds, and aerosols (Table 12).

The Portable Remote Imaging Spectrometer (PRISM) is JPL-operated airborne hyperspectral spectrometer specifically designed for coastal ocean remote sensing (Mouroulis et al, 2014). It shares many capabilities with the OCI instrument with 3.5 nm resolution in 380-1050 nm range, with SNR sitting at 500 for 450 nm[1]. It differs from OCI in that it has only two SWIR channels - 1240 and 1610 nm. The spectrophotometer's design has a total internal reflection fold, a polarization-insensitive shaped groove concave grating, a black-Si slit for uniformity and stray light reduction, and a fast, wide angle two-mirror telescope. The spectrometer is of the Dyson design form which permits a high throughput (F/1.8) and provides low angles of incidence for controlling polarization variation.

The Pushbroom Imager for Cloud and Aerosol Research and Development (PICARD) is a hyperspectral, push-broom imaging spectrometer designed to target clouds and aerosols, operated by the Airborne Sensor Facility at NASA ARC, with science and management supported by NASA

[1] https://prism.jpl.nasa.gov/spectrometer_char.html

GSFC. PICARD has 204 contiguous spectral channels in the wavelength range from 380 to 2400 nm (62 UV-VNIR, 140 SWIR) with a spectral bandpass tailored to achieve 10nm. The PICARD sensor was designed by Brandywine Photonics, LLC and consists of a dual Offner spectrometer mated to a 4-mirror wide-field anastigmat telescope. The system has a single slit and uses a dichroic beam-splitter to divide the incoming energy between the two spectrometers with cooled focal plane arrays (Si for the VNIR and HgCdTe for the SWIR). The 50° FOV (25° on either side of nadir) is unusually large for a pushbroom imager and results from a unique telescope design. This reflects a 2.1 mrad instantaneous FOV with 414 across track pixels per scanline.

Table 13 PACE-PAX airborne spectrometers characteristics compared to OCI. Note that the airborne instrument swath width and ground pixel size varies with aircraft altitude, values provided here correspond to an assumed 20km (65,000 ft) altitude of the ER-2 aircraft. See Section 13 for traceability to the VTM.

	OCI	PICARD	PRISM
UV-NIR range	Continuous from 340 to 890nm in 5-nm steps	Continuous from 380 to 2400 in 10 nm steps (62 VNIR, 140 SWIR)	Continuous from 350 to 1053.5nm at 3.5nm resolution
SWIR-IR range	0.940, 1.038, 1.250, 1.378, 1.615, 2.130 and 2.260 µm		Two channels, centered at 1.242 and 1.608µm
Swath width	±56.6˚ (2,663 km at 20˚ tilt)	±25˚, ~18.6km	±36˚, ~11km
Ground pixel	1 km at nadir	414 cross track pixels, ~45m at nadir	608 cross track pixels, ~18m at nadir (UV-NIR)

6.6.2 ER-2 Airborne multi-angle polarimeters: AirHARP, SPEX Airborne and RSP

Three different multi-angle polarimeters will be deployed aboard the ER-2 during PACE-PAX. AirHARP and SPEX Airborne instruments (characteristics in **Error! Reference source not f ound.**) are airborne proxies of the PACE HARP2 and SPEXone instruments, respectively. The Research Scanning Polarimeter (RSP), is a reference remote sensing multi-angle polarimeter, which has complementary measurement capabilities that exceed those of the proxy instruments.

AirHARP measures the same spectral and polarization bands as HARP2 (Martins et al., 2018, McBride et al., 2020, Puthukkudy et al., 2020). The difference is that AirHARP measures more viewing angles than HARP2 (a total of 120 vs 90 angles). Meanwhile, SPEX Airborne (Smit et al, 2019a,b) measures a similar spectral range and resolution as SPEXone, but with more viewing angles (nine vs five angles). RSP makes highly accurate polarimetric measurements with hyperangular distribution of 152 angles (Cairns et al 1999), with 6 VNIR and 3 SWIR bands that could prove highly useful as OCI SWIR proxy. While RSP is not an imager and has a single pixel swath, it provides high quality aerosol and cloud retrieval products (e.g., Alexandrov et al., 2018, Chowdhary et al, 2002, 2012, Knobelspiesse et all, 2011a, b, Ottaviani et al., 2018, Waquet et al., 2009), and therefore useful to evaluate the retrieval performance from the other MAP measurements.

AirHARP, SPEX Airborne, RSP and HSRL-2 (described in the next section) were deployed in the ACEPOL field campaign and successfully collected scientific data (Knobelspiesse et al 2020).

Multi-parameter retrieval algorithms have been developed from these instruments and applied to obtain aerosol properties (Gu et al 2020, Puthukkudy et al., 2020, Gao et al 2020, 2021) and ocean color signals (Gao et al 2021). ACEPOL was several years prior to the launch of PACE, so these data are valuable for algorithm development and testing. Deployed post-launch as part of PACE-PAX, they would serve as remote and proxy measurements that are at the core of many measurement objectives (see VTM for more details).

Table 14 Instrument specifications for AirHARP and SPEX Airborne. Compare to PACE HARP2 and SPEXone in Table 1. See Section 13 for traceability to the VTM.

	AirHARP	SPEX Airborne	RSP
Spectral bands (bandwidth/nm)	440 (16), 550 (12), 670 (18), 870 (39)	Continuous from 400 to 800 nm in 2-3nm steps	410 (30), 470 (20), 550 (20), 670 (20), 865 (20), 960 (20), 11590 (60), 1880 (90), 2250 (120)
Polarized bands	All	Continuous from 400 to 800 nm in 10-40nm steps	All
Cross track swath	94˚	7˚	Single pixel swath
Number of along track viewing angles	20 for 440, 550 and 870 nm and 60 for 670 nm (spaced over 114˚)	9 (0°, ±14°, ±28°, ±42°, ±56°)	152 (continuous within ± 60˚ in 0.8˚ steps)

6.6.3 ER-2 Airborne lidar: HSRL-2

Lidar instruments devoted to cloud, aerosol and ocean remote sensing are an ideal complement to the passive observations that will be made by PACE (e.g., Jamet et al., 2019). This is in part because, as active instruments, they interact differently with the geophysical state and can provide information (such as atmospheric and oceanic vertical profiles) to which passive systems are less sensitive (albeit in a narrow swath). For this reason, they can collect useful validation data as part of PACE-PAX, an approach that has been taken in previous airborne field experiments that tested passive instrument remote sensing techniques (e.g., Da Silva et al., 2020, Fu et al., 2020, Gao et al., 2020, 2021, Knobelspiesse et al., 2011a, 2020, Puthukkudy et al., 2020, Xu et al., 2021). Lidar products can be used to validate the advanced aerosol parameters for validation objective 1 (Sec 3.1), make continuous along-track measurements at nadir viewing direction for validation objective 2, and meet the narrow swath requirement for the validation objective 3.

The Lidar of choice for PACE-PAX campaign is a NASA Langley Research Center (LaRC) HSRL-2. The High Spectral Resolution Lidar (HSRL, Shipley et al., 1983) independently observes molecular and particulate return, allowing for a quantitative measurement of particulate extinction without assuming optical properties of the atmosphere, although with additional complexity and cost. The NASA Langley Research Center (LaRC) HSRL-2 has eponymous channels at 355 and 532nm, as well as a backscatter only channel at 1064nm and depolarization ratio sensitivity for all three channels (Müller et al., 2014, Burton et al., 2018). HSRL-2 is a successor of the HSRL-1 instrument (Hair et al., 2008, Rogers et al., 2009, Burton et al., 2012) and has operated since 2012. Retrievals based on HSRL-2 measurements provide standard products such as aerosol optical depth (AOD) and lidar ratio at 355 and 532 nm, as well as derived products such as aerosol mixed-

layer heights (Scarino et al., 2014), aerosol type classification (Burton et al., 2012), and aerosol effective radius and concentrations (Müller et al., 2014, Sawamura et al., 2017). Like MAPs that will be flown on ER-2, the HSRL-2 was deployed on the ACEPOL field campaign.

Table 15 summarizes HSRL-2 capabilities. b indicates sensitivity to backscatter coefficient, while a denotes extinction coefficient and d depolarization ration sensitivity. See Section 13 for traceability to the VTM.

Instrument	355nm	532nm	1064nm	Data
HSRL-2	βαδ	βαδ	βδ	Available with field campaign archives

6.7 Ground/Ocean validation sites

6.7.1 Dry lakebed surface reflectance characterization

Because of their spatially uniform topography and reflectance, unvegetated dry lakebeds (playas) can serve as a reflectance reference for overflying sensors. Observation with dedicated ground-based characterization in such locations can meet the needs of validation objective 4 in PACE VTM "Validate radiometric and polarimetric properties". Additionally, retrieval of some categories of atmospheric and surface properties can be validated (VTM measurement objectives 1A, 1D, primarily), since surface and atmospheric properties are either retrieved simultaneously, or depend on the validity of assumptions about the other. Several playas exist in the western United States that have been used for this purpose, including Rogers and Rosamond dry lakes in California, and the Railroad Valley Playa (RRV) in Nevada. To support such activities, either ground teams deploy to these locations during overpass (e.g., Knobelspiesse et al., 2020, Bruegge et al, 2021) to characterize surface BRDF, atmospheric conditions, and other relevant properties, or automated networks of instruments at recognized locations are used for the same purpose (Wenny et al, 2021). Considering our VTM, and to minimize costs, we will use the latter option. RRV hosts a site of the Radiometric Calibration Network (RadCalNet) called the Radiometric Calibration Test Site (RadCalTS), and also has an AERONET sun photometer / sky radiometer (see next section). PACE-PAX will perform overflights of this, and potentially other nearly sites.

6.7.2 Sun photometer/sky radiometers

Ground based sun photometers and sky radiometers can provide useful point validation of aerosol (and to a lesser extent, cloud) properties. Sun photometers make a direct measurement of aerosol optical depth (AOD), which defines the optical extinction of the total atmospheric column, by accurately measuring solar radiation through a narrow field of view collimator (Volz, 1959). Many can also act as sky radiometers, from which aerosol optical and microphysical properties can be retrieved (e.g., Dubovik et al., 2000). Zenith measurements in cloudy conditions can also be used to determine the cloud optical depth (COD, Marshak et al., 2004, Chiu et al, 2006, 2010).

The Aerosol Robotic Network (AERONET, Holben et al., 1998) is a federated network of hundreds of automated sun photometer / sky radiometers that use uniform data processing and archival (Giles et al., 2019, Sinyuk et al., 2020). They are the gold standard for validation of satellite aerosol data products and the network is a core component of the PVP for established PACE aerosol products. Despite this success, AERONET does have its limitations. The instruments require a non-moving stable platform, so they are located on land or a very limited

number of ocean platforms (an exception, in development, is described in Yin et al., 2019). A subset of AERONET, the Maritime Aerosol Network (MAN, Smirnov et al., 2009), is devoted to ship-based observations using handheld sun photometers. However, those measurements are restricted to AOD and a spectrally derived metric describing the ratio of fine to coarse sized aerosols. They are also constrained by the (limited) frequency of manual deployment on ships compared to continuously sampling robotic instruments that comprise the bulk of AERONET. The Ocean Color component of AERONET (AERONET-OC) is another subset comprised of instruments located on ocean platforms (Zibordi et al., 2009, 2010). AERONET-OC instruments make valuable measurements of normalized water leaving radiance in addition to standard AERONET aerosol measurements. Unfortunately, they are scarce – in the coastal USA there are only 4 of them; one in the Pacific Ocean in Southern California Bight (near Newport Beach, CA), one in the Gulf of Mexico, and three in the mid-Atlantic/New England area (one in the Long Island Sound, one in the Chesapeake Bay and one near Martha's Vineyard). Finally, we should note that the aerosol property retrieval capability of sky radiometers such as those in AERONET depend on aerosol quantity. These retrievals are highly uncertain for small amounts of aerosols (Dubovik et al., 2002), meaning that accurate systematic measurements are representative of a subset of global conditions.

In addition to ground-based sun photometer/radiometers, airborne instruments such as the Spectrometer for Sky-Scanning Sun-Tracking Atmospheric Research (4STAR, Dunagan et al. 2013, Kassianov et al., 2012) can be valuable. In addition to providing focused observations in a desired location and exploring spatial variability, specific aircraft observation patterns (such as vertical spirals) can provide profiles of aerosol properties (e.g., Shinozuka et al, 2007, 2010).

Airborne deployment of instrumentation in PACE-PAX will be augmented by AERONET with focused observations of AOD and aerosol microphysical properties over both land and ocean. When feasible, flight plans will overfly AERONET and AERONET-OC sites, linking PACE-PAX to (long term) AERONET measurements and characterizing the impact of spatial and temporal scale on satellite data product validation (validation objective 2). Because of the potential for better aerosol microphysical product retrievals with passive multi-angle polarimeters, PACE-PAX will extend validation capability to lower aerosol loads. Although not funded by PACE-PAX, flight planning will coordinate, when possible, to overfly ships deploying AERONET-MAN instruments or 4STAR if it is operating in the PACE-PAX region.

6.7.3 Vicarious calibration sites

The PACE OCI instrument will measure radiance at Top of Atmosphere (TOA), $L_t(\lambda)$ ($\mu W\ cm^{-2}\ nm^{-1}\ sr^{-1}$), in the UV-VIS-NIR wavelength range. An atmospheric correction algorithm is required to mathematically 'subtract' the contribution of the atmosphere from this TOA radiance and, thus, derive the water-leaving radiance, $L_w(\lambda)$ ($\mu W\ cm^{-2}\ nm^{-1}\ sr^{-1}$) i.e., radiance that is either reflected directly from the ocean surface or that exits through the ocean-air interface via scattering processes (see Frouin et al.(2019) and Ibrahim et al. (2019) for an overview of heritage and alternate atmospheric correction approaches). However, the desired uncertainties on $L_w(\lambda)$ retrieval cannot be achieved through instrument pre-launch calibration and characterization alone and must additionally rely upon on-orbit calibration. This process takes the form of a system level calibration, known as system vicarious calibration (SVC). The system referred to in this case is

OCI instrument and processing algorithm which takes $L_t(\lambda)$ as input and removes the atmospheric signal to produce $L_w(\lambda)$ as output. The vicarious calibration process is effectively an inversion of the forward processing algorithm, wherein a known water-leaving radiance, $L_w^t(\lambda)$, is the input and predicted TOA radiance, $L_t^t(\lambda)$, is the output, and where the superscript t indicates targeted or predicted values. The ratio of predicted to observed $L_t(\lambda)$ is the vicarious gain: the correction factor that, when applied to $Lt(\lambda)$, would force the system to yield $L_w^t(\lambda)$. A full description of the SVC process can be found in Franz et al. (2007).

SVC makes use of specific calibration sites where instrumentation has been placed for this purpose (often on buoys). These sites may also serve a role in PACE-PAX, in that they can serve as a validation of the ability to retrieve ocean radiometric parameters (validation objective 1B) or the joint retrieval of those parameters alongside aerosol parameters (validation objectives 1C). They can also be used in the SVC context for proxy instruments themselves (validation objective 4M).

The primary SVC site for all NASA ocean color satellites since 1997 (Barnes et al., 2001, Eplee et al., 2001, Franz et al., 2007) has been the Marine Optical Buoy (MOBY, Clark et al. (1997; 2003)). It is a moored buoy located approximately 20 km west of the island of Lanai in 1200 m of water with both an above and below water expression. Above the water, the main components comprise an irradiance, $E_s(\lambda)$ ($\mu W\ cm^{-2}\ nm^{-1}$), sensor, a GPS unit, a weather station, and communications components. Below the water lies an optical chain with sensor arms at 1, 5, and 9 m that measure downwelling irradiance, $E_d(\lambda)$ ($\mu W\ cm^{-2}\ nm^{-1}$), and upwelling radiance, $L_u(\lambda)$ ($\mu W\ cm^{-2}\ nm^{-1}\ sr^{-1}$). Since measurements are acquired at multiple depths, attenuation coefficients for L_u and E_d can be calculated, k_{Lu} and k_d respectively (m^{-1}), and used to propagate L_u and E_d to just beneath the water surface. These values are then used to calculate water leaving radiance, $L_w(\lambda)$ ($\mu W\ cm^{-2}\ nm^{-1}\ sr^{-1}$), which is ultimately utilized in the calculation of gain factors to vicariously calibrate on orbit satellite ocean color sensors.

In addition to MOBY, two SVC teams, which take distinctly different approaches to data acquisition methodology, were selected for a 2019 NASA funding opportunity. The first of these is the Marine Optical Network (MarONet) platform. This is essentially an upgraded version of the MOBY platform and follows the same moored buoy design with sensors located at the surface and three fixed depths. One important difference lies in the fact that updated optics and hardware allow simultaneous acquisition of $E_s(\lambda)$, $E_d(\lambda)$, and $L_u(\lambda)$. MOBY acquires each of its $L_u(\lambda)$ measurements separated by several minutes that can, potentially, result in uncertainty when combining measurements to derive parameters such as a vertical attenuation coefficient. It is intended that MarONet be deployed near the MOBY site near Lanai, and pending logistical challenges, in waters off Western Australia. Both sites have been shown to have conditions conducive to the acquisition of high-quality SVC radiometric data (Zibordi and Mélin, 2017). By deploying this system in the same area as MOBY, continuity of measurement is ensured, and new measurements can be compared with the already extensive climatology that exists at this site.

The second of these SVC platforms is the HyperNav system, a Lagrangian, profiling float which can adjust its buoyancy to operate both in a near-surface or profiling mode. The HyperNav measures hyperspectral $L_u(\lambda)$ and $E_d(\lambda)$ but is not equipped with an above water $E_s(\lambda)$ sensor. An integral part of the HyperNav measurement strategy is deployment in known physical oceanographic features intended to retain the float in the same general area for an extended period,

e.g., ocean eddies. The float's trajectory is predicted by the physical model, which helps to ensure that appropriate conditions for SVC are encountered and improves the chances of successfully retrieving the float at the end of a deployment period. HyperNav has already been deployed near the MOBY site, and future deployments will include the waters surrounding Puerto Rico. HyperNav was intended to be a fully portable system that will allow assessment of various geographical locations for SVC in contrast to the fixed location strategy of the MarONet buoy.

While the VTM shows value in basing PACE-PAX in the vicinity of the MarONet buoy in Hawaii (objective 4d), doing so would be to the detriment of many other components of the VTM. It also would carry considerable additional expense.

6.7.4 Wind buoys

Retrieval of aerosol properties over the ocean requires consideration of light interactions both within the ocean body and at the ocean-air interface. The latter can be the source of specular reflection of the direct solar beam, referred to as sun glint or glitter. Depending on sun – observation geometry, ocean surface roughness and other factors, glint can be significant enough that it must be considered in the retrieval process. In some cases, it is so large that it dominates the total signal and preclude the retrieval of other properties. The magnitude and direction of glint is driven by ocean surface roughness, the statistical distribution of the surface slopes. This roughness is linked to, and often parameterized by, surface winds (Cox and Munk, 1954). Knowledge of surface wind speed and direction is therefore important for the remote sensing of the atmosphere and ocean at geometries potentially affected by glint. In algorithms for single view angle instruments, wind speed is required as an input to either avoid or account for glint (e.g., Wang et al., 2001), whereas multi-angle instruments such as HARP2 and SPEXone have the ability to simultaneously retrieve aerosol, ocean and wind properties (e.g., Fox et al., 2007, Fu et al., 2019, Gao et al., 2021, Knobelspiesse et al., 2021, Stamnes et al., 2018).

Thus, validation of aerosol and ocean retrieval algorithms require information on surface wind vector. Fortunately, the National Oceanographic and Atmospheric Administration (NOAA) maintains an extensive network of wind speed monitoring buoys, the National Data Buoy Center (NDBC, https://www.ndbc.noaa.gov/). This network of instruments is well located, often in the immediate vicinity of AERONET-OC sites. Successful PACE-PAX flight plans will require overflights of these buoys (many of them present in the area of planned operations).

7 MISSION REQUIREMENTS

7.1 Ground resources

Careful aircraft coordination with ground observation sites will be an important aspect of PACE-PAX. Overflights should be made when ground measurements are being made, and in a manner conducive to measurement by the airborne instruments. For example, multi-angle polarimeters require long, straight flight segments so that all angles fore and aft observe a target. In many cases these instruments operate best if the flight track is aligned with the solar azimuth angle, so that the widest range of scattering angles are observed.

Figure 6 ACEPOL flight track emphasizing coordination with ground observations. AERONET and AERONET-OC sites are indicated in white, Rosamond Dry Lake with a yellow arrow. The flight track is indicated in green, and the flight began and ended near AFRT just south of Rosamond Dry Lake. For more details see Knobelspiesse et al., 2020.

Figure 6 shows an example of close aircraft – ground coordination during the ACEPOL flight on October 25, 2017. On this day, a team from JPL was deployed to Rosamond Dry Lake to characterize surface reflectance (see Section 6.7), and a 'Rosette' of five overflights at various headings were performed. Additionally, the Fresno, Bakersfield, UCSB, USC_SEAPRISM, and CalTech AERONET sites were overflown. The Bakersfield overflight was planned to be within 10˚ of the solar azimuth angle. Note that PACE-PAX is not planning to send a team to a ground site like in ACEPOL but will overfly RRV with its automated suite of instruments (see Section 6.7.3). This will satisfy objectives 1a, 1d, 4a, 4c, and 5b, among others.

7.2 Ocean surface resources

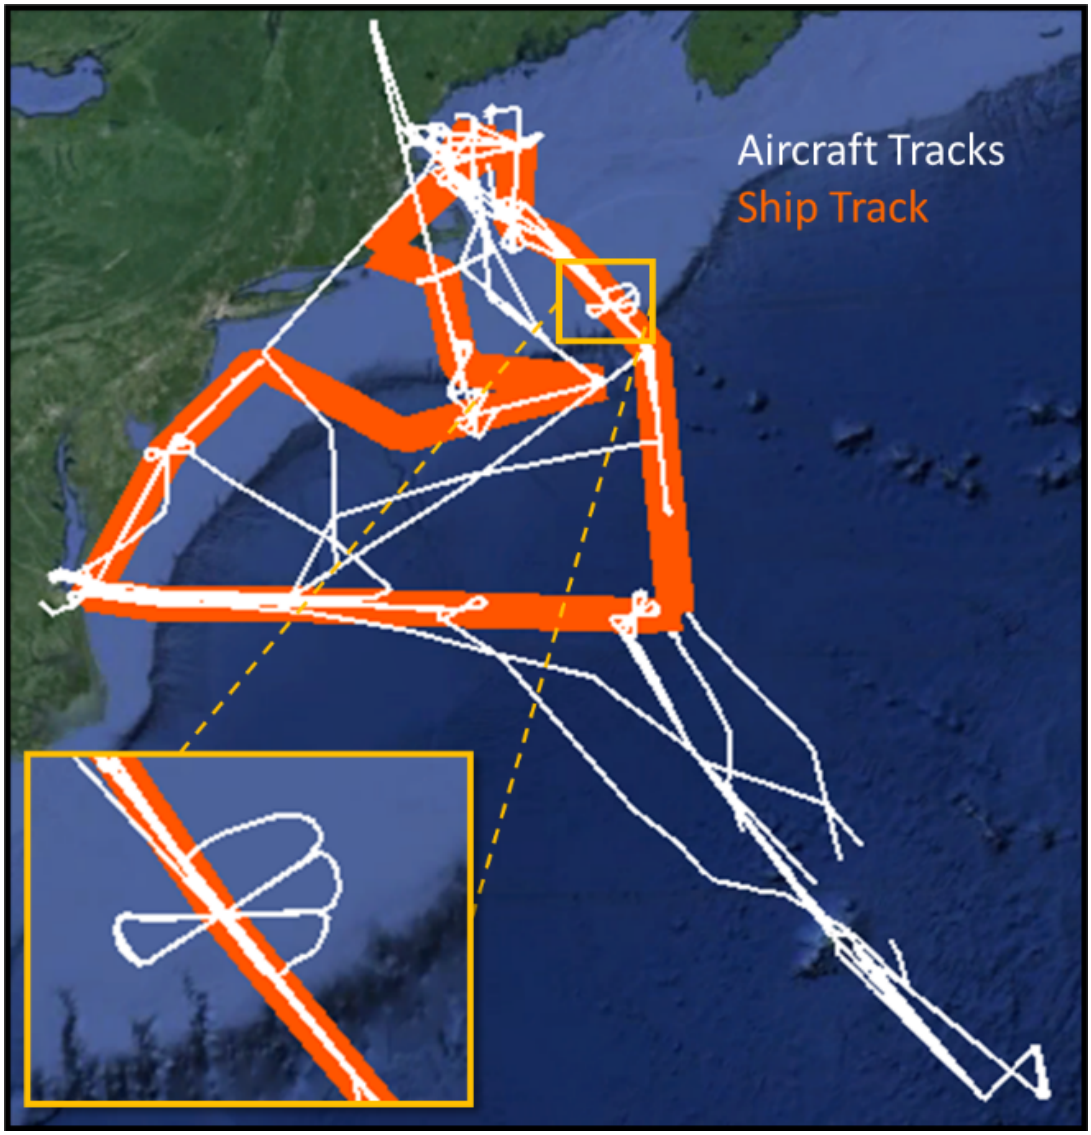

Figure 7. Aircraft tracks (white) superimposed on the ship's track (orange) during the Ship-Aircraft Bio-Optical Research Field Campaign (SABOR) field campaign in 2014 in the Atlantic Ocean. Inset on the left depicts crossing patterns over the ship to acquire RSP polarimeter data at appropriate solar angles coincident with ship-borne polarimeter measurements.

Although PACE-PAX is not directly planning for the deployment of ship-borne instrumentation, it is important to prepare for coordination with ongoing efforts to observe the ocean radiometric state and augment continuous observations by, for example, AERONET-OC sites. Ship borne, direct radiometric measurements can satisfy validation objective 1b, and contribute to validation objectives 1c, 2g, 5n, 6r, 6x, 6y and 6z. Coordinated measurements can be performed in a similar manner as with ground measurements described in the previous section but require close cooperation between the PACE-PAX and ocean observing teams, as it was done previously for NAAMES and SABOR campaigns (Figure 6). The role of the DMS will be to seek out potential planned observations at the time of PACE-PAX and within range, connect with those teams, and provide coordination during the field campaign.

7.3 Satellite coordination

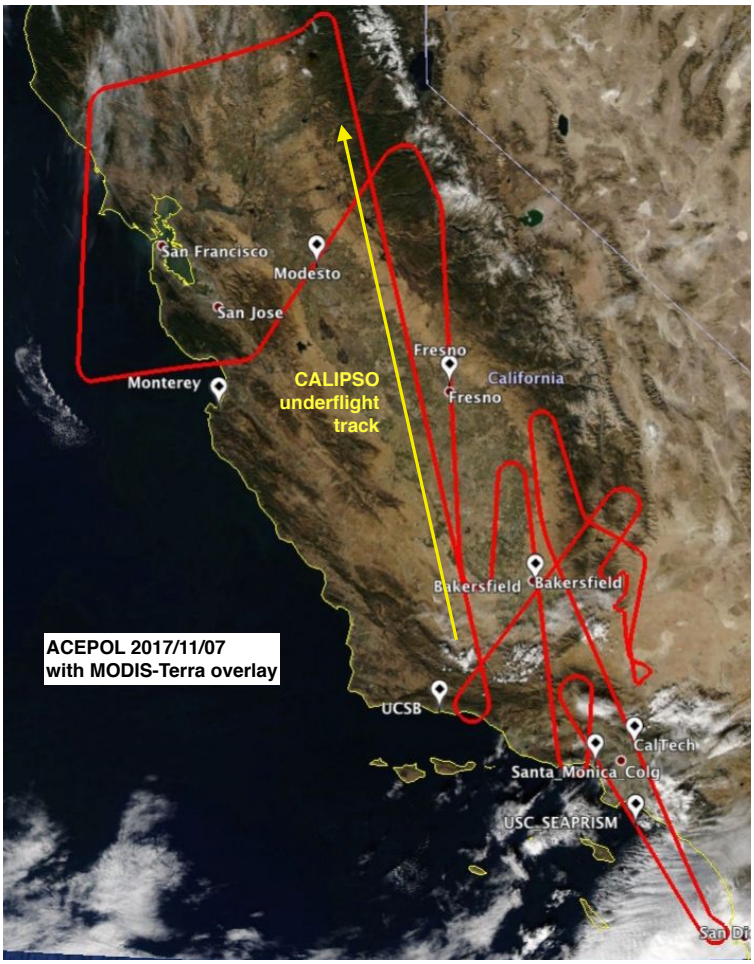

Figure 8 ACEPOL flight track coordinated with CALIPSO overflight. The flight track is in red, and the portion made in the CALIPSO track is indicated with the yellow arrow. The CALIPSO overflight time was 21:18 UTC, while the sample leg was started at 21:05 UTC and ended at 21:49 UTC. On this day AERONET sites (in white) and cirrus clouds to the southeast were also observed. For more details see Knobelspiesse et al., 2020.

Coordinated under-flights of PACE is the primary requirement of validation objective 3, "Validate in a narrow swath" and for validation with measurements that are classified as 'direct' or 'remote' in Section 3.6 (unless those measurements are in support of a 'proxy' measurement). Predictions of satellite flight path will be obtained by the PACE-PAX DMS and incorporated with weather forecasts for the purposes of flight planning. Flight plans satisfying this requirement for instruments in ascending polar orbit like PACE have long, roughly South to North paths, at time of overpass. For example, the ACEPOL field campaign made three CALIPSO or Cloud-Aerosol Transport System (CATS, McGill et al., 2015, Yorks et al., 2016) under-flights. Considering the high importance of objective 3 (and that satisfying it will also satisfy other objectives), we expect to make a larger fraction of observations in this mode. Figure 8 is an example of a flight during the ACEPOL field campaign that performed an under-flight of CALIPSO.

7.4 Data management plan

Data generated during the PACE-PAX will follow the NASA Earth Science Data and Information Policy (https://science.nasa.gov/earth-science/earth-science-data/data-information-policy/data-rights-related-issues) which requires data to be available from a designated long-term repository within a year of collection. Similar to other successful NASA campaigns, PACE-PAX will involve data manager(s) from the early stages of planning to ultimately facilitate data submission and distribution. All data collected during PACE-PAX will be shared, in preliminary format, within 3 months of collection, and in final format within 6 months of collection.

Following the field deployment stage of PACE-PAX, we would like to hold one or several PACE-PAX data workshops. The goal of these workshops is to discuss the data that were collected during the field campaign, what was and was not accomplished, and how to access and analyze the data. We will also publish our results in a data journal, such as Earth System Science Data (https://www.earth-system-science-data.net/).

7.5 Risk assessment

Risk assessment is made in accordance with "NASA accepted Continuous Risk Management in accordance with NPR 7120.8D and NPR 8000.4" and held by the PACE-PAX PM, with input from MS, AM, WF.

#	Risk	Background	Response / Mitigation	Like-lihood	Consequence
A	PACE launch delay	PACE may launch later than expected.	Delay	1	4 Aircraft or instruments may not be available with delayed schedule. Optimal observation conditions may be missed.
B	PACE spacecraft failure	Full launch or spacecraft failure of the PACE mission.	Cancellation	1	5 Eliminates the need for PACE validation, although PACE-PAX may be useful for other NASA objectives
C	Individual PACE instrument failure	Full individual instrument failure upon successful launch.	Descope of PACE-PAX	1	3 Fully planned validation mission would be descoped as described in previous sections, keeping the timeline so the optimal observation condition are captured.
D	PACE instrument data delivery delay	Fully calibrated data not available at the planned time point	Delay	2	3 Aircraft or instruments may not be available with delayed schedule. Optimal observation conditions may be missed, or not immediately assessable.
E	Aircraft failure	Aircraft failure close to beginning or during PACE-PAX	Delay	2	4 (New) aircraft or instruments may not be available with delayed schedule. Optimal observation conditions may be missed.

F	Individual PACE-PAX instrument failure	An aircraft instrument in PACE-PAX fails to operate prior to or during the mission	Select instruments that have established successful heritage. Redundant observations.	2	2 Consequence depends on the nature of failure and impact on objectives
G	Optimal observation conditions are not encountered	Measurement conditions required in the VTM are not encountered (for example, insufficient aerosol loads)	Based on climatological assessments, estimate and provide sufficient margin on schedule and flight hours	3	1 VTM is organized for multiple objectives that rely on measurement conditions
H	Unexpected extreme weather event(s)	Extreme environmental conditions along planned flight path or at BOP (e.g., hurricane, earthquake) result in extended suspension of flight operations	Modify/delay PACE-PAX plan	1	4

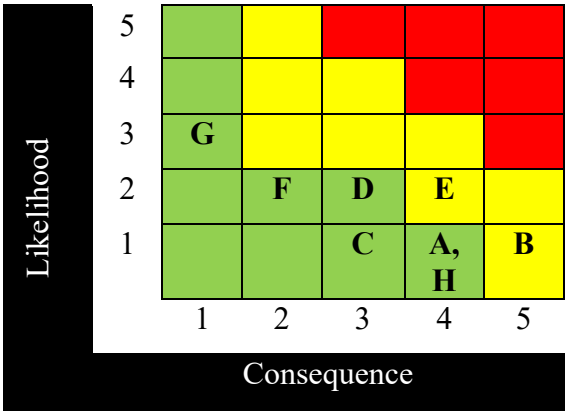

Figure 9 PACE-PAX risk matrix

7.6 Expectations for a safe fieldwork culture

PACE-PAX is committed to provide respectful and inclusive environment for all who participate in this field campaign. However, we acknowledge that these isolated settings, such as PACE-PAX field campaign, have shown to amplify the risks of harassment and bullying, toxic climates and interpersonal power imbalances, causing further marginalization of the under-represented groups in our field. With that in mind and following recommendation of previous successful campaigns, field stations, and working groups, PACE-PAX will provide a suite of tools to insure a safe fieldwork culture for all.

Leadership of PACE-PAX will be responsible to provide a Code of Conduct that all participants, regardless of the institutional background, need to adhere by. This code of conduct will rely on existing institutional policies and new ones specific to PACE-PAX, including sexual misconduct policy, alcohol and drug policy, pregnancy and lactation policy, COVID-19, privacy, hygiene, and other topics. Leadership of PACE-PAX will do an early identification of potential challenges for the operational bases including:

a. analysis of diversity of local community vs diversity of the science team,
b. identification of language/cultural/legal differences that might present personal safety challenges including access to communication.

Identification of these challenges, and PACE-PAX strategies to address them will become part of the Code of Conduct, that will be available and communicated to participants up to 6 months prior to the campaign. A digital and printed version of the PACE-PAX code of conduct will be available to all participants throughout the campaign.

All participants will be required to present the proof of completion of their institutional harassment training and participate in any additional host institution trainings. PACE-PAX will require a bystander training from all participants and provide that training prior to the field campaign.

Leadership of PACE-PAX will provide clear incident reporting and communication plan; identify emergency resources available to the team members, establish (confidential) reporting channels with clear chain of command, and outline clear response activities in case of incidents.

7.7 Connection with PACE Applications

While PACE-PAX is not directly planning to do any work that directly supports the PACE Applications Program, it may be a potential opportunity for a value-added, applications related activity. This document will be shared with the PACE Community of Practice (CoP) and PACE Early Adopters, welcoming any parallel data collection activities with PACE-PAX. The PACE-PAX deputy mission scientist(s) will be available to connect with those teams and provide coordination during the field campaign if needed.

8 GUIDING FIELD CAMPAIGNS UNDERWAY

The success function, *S* (equation 5), is also a tool for planning an underway field campaign. It is used to help prioritize allocation of resources based upon the importance of validation objectives, completeness of the instrument suite, fulfillment of validation objectives thus far, and probability of future validation success. It identifies which of the measurement objectives will contribute the most to increasing the overall value of the success function. To do so, we consider the individual terms (each corresponding to a measurement objective) within the summation comprising *S.* More specifically, we identify the derivative of each measurement objective term with respect to time, *t*:

$$\frac{d}{dt_i}\left(S_i(t_i)\right) = c_i z_i \frac{p_i}{h_i} e^{-\frac{t_i p_i}{h_i}} \tag{6}$$

Note here that t_i now refers to observation of a specific measurement objective, and represents time spent *successfully* making observations that satisfy a measurement objective. Furthermore, p_i

now represents probability of success specifically for the next increment of mission planning time, instead of for the duration of the mission.

This approach can be used, for example, for airborne field campaign flight planning by incorporating success thus far (t_i) and weather dependent probability of success in a subsequent day (p_i). To demonstrate, we use equation (6) to plan the Alpha theoretical field campaign. This is shown in Table 16.

The flight planning for day 1 of field campaign Alpha would use equation 6 to determine the success function derivative for each measurement objective. To start, we presume the probability of success is the same as was used in Section 5. In other words, the weather prediction is the same as climatology. Both measurement objectives A and B have identical high values of $S_i(t_i)'$. This is because they have equal probability of success, and because the greater weight of objective A is balanced by the smaller measurement time required for objective B. The decision, then, is to split the coming eight-hour flight (a typical flight length) equally among both objectives.

Let us now presume that the flight on day 1 was successful, and four hours of measurements have been made for each of objective A and B. We take this into account for the assessment for day 2. Furthermore, the weather predictions have changed, along with the corresponding probability of success. Recalculation of $S_i(t_i)'$ compels us to devote the entirety of the flight on day 2 to objective D.

Now we assume that we were mostly successful on day 2 and made six hours of observations in an eight-hour flight. We have largely satisfied the time required for objective D, which is 5 hours, defined in equation 1 as the time required to satisfy the objective to 63%. If the weather stays the same for day 3, then our success function would direct us to refocus on measurement objective A, which has a lower probability of success but has thus far been less completely measured.

Table 16 Field campaign Alpha underway planning. This table illustrates how the derivative of the success function can be used to prioritize which measurement objectives to target on a given day, given weather (and other factor) driven probability of measurement success, plus information about the number of successful measurements have been made thus far. Boldfaced, white background values of $S_i(t_i)'$ indicate selected objectives for a given day.

Field campaign configuration				**Day 1**			**Day 2**			**Day 3**		
Meas. objective	**Weight, *w***	**Time required, *h***	**Completeness, *c***	**t_i**	**Prob. of success, *p***	**$S_i(t_i)'$**	**t_i**	**Prob. of success, *p***	**$S_i(t_i)'$**	**t_i**	**Prob. of success, *p***	**$S_i(t_i)'$**
A	4	20	1.0	0	0.50	**0.011**	**4**	0.50	0.010	4	0.50	**0.010**
B	2	10	1.0	0	0.50	**0.011**	**4**	0.50	0.009	4	0.50	0.009
C	2	15	0.0	0	0.10	0.0	0	0.75	0.0	0	0.75	0.0
D	1	5	1.0	0	0.10	0.002	0	0.75	**0.017**	**6**	0.75	0.007

In this manner, we can manage a field campaign that is underway, and account for measurements that have been made with varying probabilities of success. We have given an example for an airborne field campaign, for which decisions of measurement priority are complex, involve constantly changing and uncertain information (weather and other factors), and must be made

rapidly. Sometimes, the weather or other conditions may be such that it is best not to perform a flight at all. In these cases, the values in $S_i(t_i)'$ would all be low. The decision to not perform a flight may depend on this and other factors, such as flight hours remaining, personnel, aircraft or other availability, and success thus far. As a metric to describe the latter, we define the mission completeness function, M:

$$M = \sum_{i=1}^{n} c_i z_i \left(1 - e^{-\frac{t_i}{h_i}}\right) \tag{7}$$

here t_i refers to the successful measurements for the i^{th} objective thus far, and probability of success is not included. At the start of a field campaign, $M=0$, and it increases until $M=V$, where V is validation instrument potential. If successful measurements have been made for times equal to the required observation time, h, for each objective, then M will have a value roughly 63.2% as large as V. If measurements have been made for three times h, then M will be 95% as large as V. In the example above, $M=0.153$ (19.8% of V) after the first day, and $M=0.2315$ (29.8% of V) after the second. This metric can be used to determine when a field campaign is 'done'. It roughly tracks the curve shown in Figure 2.

As previously noted, this approach has similarities with search and rescue theory described in Stone (1989) and elsewhere. In our case, each measurement objective can be considered a search area bin, and the corresponding elements of the success function derivative are a probability distribution function indicating the optimal bins in which to search. These are updated with subsequent measurements. As in any analysis incorporating subjective parameters, its realism depends upon how well these parameters were chosen. The benefit of these techniques is in their ability to break down complex conditions into simple assessments.

These tools will be used to perform flight planning during the operational phase of PACE-PAX. Flight planning will be aided by the "Moving Lines" software developed in Leblanc, 2018. This creates a flight path that can be submitted to the aircraft crew, which accounts for aircraft constraints, target location, solar geometry, (restricted) Special Use Areas (SUA), and other considerations.

Additionally, we expect to have one or more dry run flight planning activities in the months prior to PACE-PAX operations. The results of these activities can be assessed on how successfully measurement objectives would have been met had the aircraft flown that day.

9 STATISTICAL CONSIDERATIONS

Any measurement or retrieval includes some uncertainty, and any data collected represent only a sample of the real-world spatial and temporal covariation between the relevant geophysical parameters. Thus, the analysis of PACE-PAX (or any other) field campaign measurements is an inherently statistical enterprise, and the way that the data are compared, and which metrics are chosen to assess performance or consistency, are important and not necessarily the same for each geophysical quantity. Here we present some statistical considerations relevant to the eventual analysis of the data.

Traditionally, two data sets are often compared using a scatter plot, with linear ordinary least-squares regression metrics (such as fit intercept and slope, Pearson's correlation coefficient, and standard deviation or root mean square difference) reported to quantify agreement. However, this approach relies on a number of important assumptions which are often violated by our real-world geophysical data and applications, i.e., independent draws from the distribution of the true state; a linear model being the correct one to describe the relationship; a Gaussian distribution of deviations from the linear model; no uncertainty on the reference data or from the matchup technique (see discussion in Seegers *et al.*, 2018).

The violation of these assumptions has varying consequences in different situations. For example, small absolute uncertainties can nonetheless lead to a low Pearson correlation if the range of the parameter sampled is small. Or, if a retrieval performs very well but has one significant outlying failure case. Conversely, if a higher-uncertainty retrieval happens to sample an extreme outlier and recognize that it is an outlier (but misrepresent its magnitude) than a high correlation can be obtained. All these situations arise because Pearson correlation is not a measure of agreement but rather of degree of linear covariation, with deviations penalized on a squared basis.

Uncertainties in the reference measurement and spatio-temporal variation are important because these contribute to the discrepancy in the comparison but are not reflective of an actual error in the retrieval. Thus, a failure to account for them overstates the level of error in the data product being validated (Virtanen *et al.*, 2018; Sayer, 2020). This is a motivation for understanding the scales of variation of the data sampled in PACE-PAX (Objective 2 in Table 7). As a result, we propose the use of methods and metrics which account for the varying factors, which can affect the basic commonly reported validation metrics. Specifically, these methods include:

1. Ways to assess the consistency between reference and retrieval across the range of the parameter and in different conditions. Examples include the use of Bland-Altman assessment as an addition (or alternative) to scatter plots (Knobelspiesse *et al.*, 2019; McKinna *et al.*, 2021), and the subsetting of data into relevant subcategories, e.g., liquid vs. ice phase clouds, maritime vs. smoke-dominated aerosol loads, observations over land vs. Water (Sayer *et al.*, 2014).

2. Ways to assess uncertainty estimates reported by retrieval techniques (which are expected from most Project Science and SAT algorithms). These methods should account for the uncertainty in the reference data set (which is, in many cases, known) as well as the potential representativeness uncertainty introduced by spatiotemporal differences in the sampling of reference vs. Retrieval (Sayer, 2020; Sayer *et al.*, 2020).

3. Ways to assess to what extent the probability distribution function of retrieved quantities follows that observed by the airborne data (Platnick *et al.*, 2017; Sayer & Knobelspiesse, 2019), including relevant inter-parameter covariations if applicable (Marchand, 2013). This is relevant because many metrics (e.g., mean bias) only capture the overall bias tendency and do not reflect whether the variation in that parameter is reasonable (e.g., too wide or narrow, unrealistic skew/modes).

While methods may need to evolve dependent on the type and quality of data that are collected, the guiding principles are to, as far as possible, avoid, the use of analyses and metrics that are reliant on assumptions that may not be valid, and to validate the uncertainty model associated with a data product as well as the product itself. We acknowledge that a single field campaign cannot fully resolve all the above questions, but through achieving the Objectives listed in Table 7, it is expected that available capabilities and conditions should be sufficient to provide an understanding of performance over a variety of conditions.

10 CONCLUSIONS

The PACE-PAX field campaign is envisioned to meet the post-launch validation objectives of the PACE mission, especially those related to new products that cannot be met with the PVP alone. Because these objectives are varied, we have developed the VTM to show how validation objectives relate to measurement objectives, geophysical parameters, and mission requirements. We have also developed a scheme to qualitatively assign importance to individual objectives, along with other metrics that help in trade studies during mission design and flight planning during the campaign itself. This was used in the planning for the specific PACE-PAX field campaign, devoted to serving the needs of PACE mission validation.

11 ACRONYMS

4STAR	Spectrometer for Sky-Scanning Sun-Tracking Atmospheric Research
ACE	Aerosol-Cloud-Ecosystems
ACEPOL	Aerosol Characterization from Polarimeter and Lidar
ACTIVATE	Aerosol Cloud meTeorology Interactions oVer the western ATlantic Experiment
AERONET	Aerosol Robotic Network
AERONET-OC	Aerosol Robotic Network – ocean color component
AFRC	NASA Armstrong Flight Research Center
AirMSPI	Airborne Multiangle SpectroPolarimetric Imager
AirHARP	Airborne version of Hyper-Angular Rainbow Polarimeter
AM	Aircraft Manager(s)
AOD	Aerosol optical depth
ARC	Ames Research Center
ASP	Airborne Science Program
AVIRIS-NG	Airborne Visible / Infrared Imaging Spectrometer – Next Generation
BRDF	Bidirectional Reflectance Distribution Function
BST	Bayesian search theory
CALIPSO	Cloud-Aerosol Lidar and Infrared Pathfinder Satellite Observation
CAMP2Ex	Cloud, Aerosol and Monsoon Processes Philippines Experiment
CAPS	Cloud Aerosol and Precipitation Spectrometer
CAS	Cloud and Aerosol Spectrometer
CATS	Cloud-Aerosol Transport System
CDP	Cloud Droplet Probe
CIP	Cloud Imaging Probe
CIRPAS	Center for Interdisciplinary Remotely Piloted Aircraft Studies
COD	Cloud optical depth
CPL	Cloud Physics Lidar
DM	Data Manager(S)
DMS	Deputy Mission Scientist(s)
DoD	Department of Defense
ESDS	NASA Earth Science Data Systems
EXPORTS	EXport Processes in the Ocean from Remote Sensing
FIREX-AQ	Fire Influence on Regional to Global Environments and Air Quality
FSSP	Forward Scattering Spectrometer Probe
GARP	Global Atmospheric Research Program
GISS	Goddard Institute for Space Studies
GSFC	Goddard Space Flight Center
HARP2	Hyper-Angular Rainbow Polarimeter 2
HQ	NASA Headquarters
HSRL-2	High Spectral Resolution Lidar – 2
HyspIRI	Hyperspectral Infrared Imager
ImPACT-PM	Imaging Polarimetric Assessment and Characterization of Tropospheric Particulate Matter
ISARA	In-Situ Aerosol Retrieval Algorithm
IS	Instrument Scientist(s)

JPL	Jet Propulsion Laboratory
LACIE	Large Area Crop Inventory Experiment
LaRC	Langley Research Center
LARGE	Langley Aerosol Group Experiment
L1Cplan	PACE Level 1c data format
LWC	Liquid Water Content
MAIA	Multi-Angle Imager for Aerosols
MAN	Maritime Aerosol Network
MAP	Multi-Angle Polarimeter
MAPP	Microphysical Aerosol Properties from Polarimetry
MarONet	Marine Optical Network
MAS	MODIS Airborne Simulator
MERRA-2	Modern-Era Retrospective analysis for Research and Applications
MRD	Mission Requirements Document
MOBY	Marine Optical Buoy
MODIS	Moderate Resolution Imaging Spectroradiometer
MS	Mission Scientist
NASA	National Aeronautics and Space Administration
NDBC	National Data Buoy Center
NIR	Near infrared

13 TABLE OF MEASUREMENTS APPENDIX

Table 17 Table of PACE-PAX aircraft deployed measurements

	Name	Validation Objective	POC
Weather forecasting data			
	Custom weather forecast maps	n/a	Rei Ueyama, NASA ARC
	Custom format satellite data	n/a	
	Custom aerosol model data	n/a	
ER-2 AirHARP instrument			
	Level 1c multi-angle polarimetry (PACE/HARP2 Proxy)	1a, 1b, 1c, 1d, 1e, 1f, 2a, 2b, 4a, 4b, 4c, 5a, 5b, 5c, 6a, 6b, 6c, 6d, 6e, 6f, 6g, 6h, 6i, 6j, 6k	Vanderlei Martins, UMBC
ER-2 HSRL-2 instrument			
	Lidar Level 2 vertically resolved atmospheric data	1c, 1d, 1e, 2a, 2b, 3c, 6a, 6b, 6c, 6d, 6e, 6f, 6g, 6h, 6i, 6j, 6k	Johnathan Hair / Taylor Shingler, NASA LaRC
	Lidar Level 2 vertically resolved ocean data	1b, 1c, 3a, 5a, 6b, 6g, 6h, 6i, 6j, 6k	
ER-2 PICARD instrument			
	UV-SWIR imaging spectroscopy (380-2400), L1c	1a, 1b, 1c, 1d, 1e, 2a, 2b, 3b, 4a, 4b, 4c, 5a, 5b, 5c, 6a, 6b, 6c, 6d, 6e, 6f, 6g, 6h, 6i, 6j, 6k	Kerry Meyer, NASA GSFC
ER-2 PRISM instrument			
	UV-SWIR imaging spectroscopy (380-1050), L1c	1a, 1b, 1c, 1d, 1e, 2a, 2b, 3b, 4a, 4b, 4c, 5a, 5b, 5c, 6a, 6b, 6c, 6d, 6e, 6f, 6g, 6h, 6i, 6j, 6k	David R Thompson, JPL
	PRISM+PICARD L1c PACE/OCI proxy product	1a, 1b, 1c, 1d, 1e, 2a, 2b, 3b, 4a, 4b, 4c, 5a, 5b, 5c, 6a, 6b, 6c, 6d, 6e, 6f, 6g, 6h, 6i, 6j, 6k	Kerry Meyer, David R Thompson, NASA GSFC / JPL
ER-2 RSP instrument			
	Level 1c multi-angle polarimetry	1a, 1b, 1c, 1d, 1e, 1f, 2a, 2b, 3b, 4a, 4b, 4c, 5a, 5b, 5c, 6a, 6b, 6c, 6d, 6e, 6f, 6g, 6h, 6i, 6j, 6k	Brian Cairns / Kenneth Sinclair, NASA GISS
ER-2 SPEX Airborne instrument			
	Level 1c multi-angle polarimetry (PACE/SPEXone Proxy)	1a, 1b, 1c, 1d, 1e, 2b, 3a, 3b, 3c, 4a, 4b, 4c, 5a, 5b, 5c, 6a, 6b, 6c, 6d, 6e, 6f, 6g, 6h, 6i, 6j, 6k	Otto Hasekamp, SRON
CIRPAS Twin Otter facility instruments			
	Navigation	n/a	Anthony Bucholtz, NPS
	Meteorology	n/a	
	Wind	n/a	

	Ultra-Fine 3025A particle counter	1e, 2a, 3c, 5c, 6e, 6f	
	Magic200 CPC particle counter	1e, 2a, 3c, 5c, 6e, 6f	
	TSI Scattering Nephelometer	1c, 1d, 2b, 3a, 3b, 5a, 5b, 6a, 6b, 6c, 6d, 6e, 6g, 6h, 6i, 6j, 6k	
	Particle soot absorption photometer (PSAP)	1c, 1d, 2b, 3a, 3b, 5a, 5b, 6a, 6b, 6c, 6d, 6e, 6g, 6h, 6i, 6j, 6k	
	PMS PCASP	1c, 1d, 2b, 3a, 3b, 5a, 5b, 6a, 6b, 6c, 6d, 6e, 6g, 6h, 6i, 6j, 6k	
	DMT Cloud Imaging Probe (CIP)	1e, 2a, 3c, 5c, 6e, 6f	
	DMT Cloud and Aerosol Spectrometer (CAS)	1c, 1d, 1e, 2a, 2b, 3a, 3b, 3c, 5a, 5b, 5c, 6a, 6b, 6c, 6d, 6e, 6f, 6g, 6h, 6i, 6j, 6k	
	DMT Hotwire Liquid Water Content (LWC)	n/a	
LARGE suite on CIRPAS Twin Otter			
	DMT Ultra-High Sensitivity Aerosol Spectrometer	1c, 1d, 2b, 3a, 3b, 5a, 5b, 6a, 6b, 6c, 6d, 6e, 6g, 6h, 6i, 6j, 6k	Luke Ziemba, NASA LaRC
	TSI-3321 Aerodynamic Particle Sizer (APS)	1c, 1d, 2b, 3a, 3b, 5a, 5b, 6a, 6b, 6c, 6d, 6e, 6g, 6h, 6i, 6j, 6k	
	TSI-3563 Scattering Nephelometer, Dry	1c, 1d, 2b, 3a, 3b, 5a, 5b, 6a, 6b, 6c, 6d, 6e, 6g, 6h, 6i, 6j, 6k	
	TSI-3563 Scattering Nephelometer, Humidified	1c, 1d, 2b, 3a, 3b, 5a, 5b, 6a, 6b, 6c, 6d, 6e, 6g, 6h, 6i, 6j, 6k	
	Aerodyne CAPS-PMSSA at RH < 40%	1c, 1d, 2b, 3a, 3b, 5a, 5b, 6a, 6b, 6c, 6d, 6e, 6g, 6h, 6i, 6j, 6k	
LiNeph on CIRPAS Twin Otter			
	Laser Imaging Nephelometer (LiNeph)	1c, 1d, 2b, 3a, 3b, 5a, 5b, 6a, 6b, 6c, 6d, 6e, 6g, 6h, 6i, 6j, 6k	Adam Ahern, NOAA

Table 18 Externally supported measurements

	Name / location	**Type/location**	**Observed geophysical parameters**	**Validation Objective**	**Archive**
Railroad Valley (RRV) Radiometric Calibration Test Site (RadCalTS)					
	RadCalNet	downward looking radiometers	surface bidirectional reflectance factor	1a, 1d, 4a, 4c, 5b	www.radcalnet.org
	AERONET Railroad_Valley	sun photometer, sky radiometer	spectral aerosol optical depth, microphysical properties	1a, 1d, 4a, 4c, 5b	aeronet.gsfc.nasa.gov
Aerosol Robotic Network					

	AERONET (land)	sun photometer, sky radiometer		1a, 1d, 1e, 4a, 4c, 5b, 5c, 6a, 6c, 6d, 6g	aeronet.gsfc.nasa.gov
	AERONET-OC (Ocean)	sun photometer, sky radiometer, above water ocean radiometer	spectral aerosol optical depth, microphysical properties, normalized water leaving radiance	1b, 1c, 5a, 6b, 6c, 6g, 6h, 6i, 6k	aeronet.gsfc.nasa.gov
	AERONET-MAN	ship based hand held sun photometer	spectral aerosol optical depth	1b, 1c, 5a, 6b, 6c, 6g, 6h, 6i, 6k	aeronet.gsfc.nasa.gov
National Data Buoy Center (NDBC)					
	Buoys	Numerous ocean sites	Wind speed, other meterological information	1b, 1c, 1f, 1a, 4b, 5a, 6b, 6g, 6h, 6i, 6j, 6k	www.ndbc.noaa.gov
